I hate the looks of the circle on the SP-830.speaker. I much prefer the look of the SP-820 speaker. Would a SP-820 speaker which does not have this stupid circle on the front of it's face match my TS-830S in size and color as I would much prefer it's look.

Any insight on all this would be appreciated. I am looking forward to receiving my TS-830S. I have never had one before and have always admired them. I am used to Drake equipment but I know the Kenwood rigs sound great. It took me awhile to get one but that will finally now happen.

Lee,
Congrats on your purchase. You'll find the 830's great to have and to operate.
I have not heard of an SP-830. The SP-230 & SP-820....yes.I agree with you regarding the SP-820 vs the SP-230. Both external speakers have pretty much the same innards....3 filters, 2 different audio inputs...and a phone jack on the front panel. The case color is very close to being the same...but due to age...and environment, will probably not match exactly. The face plate may also suffer from the above.Keep in mind that each speaker was designed for a specific rig series...cases can be be repainted...front panels with the silk screening...just a real pain. If you don't mind a possible small color mismatch the SP-820 will work fine..you'll have to make up an interconnect cable in either case...1/8" male (mono) to RCA plug, and what ever length of shielded audio cable you want.

All Kenwood hybrids have speakers already in them...unless someone has removed it.They are mounted on underside of the top cover and function OK. For any length of listen time, my SP-820 is just fine...you can play with filter selection combinations...I often use headphones.
Good luck and have fun with your new "toy!"

Thanks, Joe,

I do see both SB-230 and SB-220 speakers on Ebay. The SB-220 on Ebay looks just like a SB-230. All this seems very strange. Apparently the SB-230 is rare and hold a stiff price. I could care less about that issue. To me, the SB-220 looks great so that is what I will buy. Again thanks for the help.

Yes, Lee, the SP-820 has the same 8 ohms audio impedance the SP-830 has which will work fine with the TS-830.

Both radios have the same audio amplifier output impedance range of 8 to 16 ohms. You can find the audio impedance range for the TS-820 and TS-830 transceivers listed on the individual radio's operator manual's "specification" page (TS-820 and TS-830 page 3).

If the operator and service manuals are not included with your newly acquired TS-830S then you can download them free from my website

www.w5rkl.com

Click on the "Manuals and Documents" link at the top of the page. When the page comes up, scroll down to listing #17 TS-830 operators manual, #19 TS-830 service manual, and #20 TS-830 excellent schematic, one at a time. Each document will download to your computer in pdf format.

While the temptation is high to plug your newly acquired TS-830S into the wall outlet then power up the radio, do not give in to that temptation. Spend time reading/studying the TS-830 "operator's manual" before you power up the TS-830. Pay attention to the front and rear panel control pages, learn what each front and rear panel control is for and how to use them. Study the section on setting the 60ma final amplifier idling current. Study the section on transmitter tuning.

If you do not have a 50 ohm dummy load, I recommend you purchase one that has a power rating of at least 300 watts. A good 300 watt dry 50 ohm dummy load is the MFJ-260C. You can download the MFJ-260C dummy load manual at the following MFJ link

http://www.mfjenterprises.com/Downloads/index.php?productid=MFJ-260C&filename=MFJ-260C.pdf&company=mfj

The MFJ-260C is a very good 50 ohm dry dummy load just pay close attention to the maximum 90 second continuous 100 watt carrier time period with a 2 to 3 minute cool down period. This is stated in the MFJ-260C manual available free at the above MFJ link.

You should tune your transmitter(s) up into a 50 ohm dummy load.

Carlos,
First, check to see if the "SG" switch on the rear panel is "ON."The model of your rig would be nice to know...IF you get no ALC...is it when you are in "tune" mode? If so..you may have an increased value of the two resistors the make up a voltage divider circuit that is used in the tune mode. Depending on your rig they could be: R-15 & 16 on the rectifier board of the 830S or R-5 & R-6 on the TS-820 HV board. They are difficult to measure "in circuit." Take voltage measurement at the "TUN" terminal post of the 820 HV board...or "TUN" terminal post of the 830S rectifier board.

You may also have a bad driver tube/socket, bad/inoperable final amp tube(s)

I could be wrong but I believe Carlos said in his initial posting that his KW hybrid radio was a TS-820. If that's true then Carlos you need to check resistors R5 and R6 on the TS-820's HV Unit board. Both resistors are 56K 1/2 watt.

A quick check can be perform by tuning the transmitter up in "CW" mode. If you can tune the transmitter up in CW mode then R5, R6, or both resistors on the TS-820 HV Unit board are causing your problem.
R5 and R6 form a resistive voltage divider, reducing the final amplifier screen voltage by 50%. R5 and R6 are in series to ground with the Rectifier Unit's 210A supply voltage. Let's assume the 820's 210A supply voltage is 255VDC which is applied to the HV Unit's "210" terminal. The total resistance of the voltage divider consisting of R5 and R6 is 112K ohms. With 255VDC applied to the voltage divider, a current of 2.3ma flows in both R5 and R6 (255 / 112000 = .00227). I rounded off the answer to 2.3ma (.0023). This results in a voltage drop across R6 of 129VDC (.0023 x 56000 = 128.8). Again I rounded off the voltage to 129VDC. With the MODE switch set to TUNE, the HV Unit's "Tune" terminal voltage is "129VDC" which is applied to pin 3 of the 6146 tube socket reducing the 6146 screen voltage by approximately 49% thereby reducing the final amplifier's DC input power in TUNE mode.

If you find either R5 or R6 out of tolerance (typical tolerance is 10%) then replace both resistors with new 56K 1/2 watt from mouser.com.

73Mike W5RKL

Topic: 52406 Message: 52410

You dont need to have the SG switch on if all you want to do is test the Driver Stage. No 6146 screen grid voltage is required in Tune or CW mode to have ALC indication????

All you need for ALC indication is:
1. 6146 Cathode emission
2. Proper operating bias voltage on the 6146 control grids
3. Sufficient RF drive voltage level at the control grids to overcome the DC offset that the bias presents (approx 47 rms rf volts).

I have posted on how to test the Driver Stage many times. You do this so you are not taxing the Final tubes needlessly loading on each band and perhaps repeatedly.

Search on message 49369 for example.

Just make sure to let the Driver Tube rest between bands as it is running Class A and will get pretty hot if key down too long.

After you prove that you have a good Driver Stage you can turn on the SG switch and then try to load in CW mode (assuming you cant load in Tune mode). Now of course you will need Screen grid voltage for RF output at the SO-239.

No point in troubleshooting loss of 6146 final tube screen grid voltage when you dont have any ALC indication. There is no relationship.

First simple thing to try when you have no ALC indication is try another known good 12BY7A tube.

Whoops sorry about that.

TS-520S

SG is set to on.

I tried another driver tube that I pulled out of another project radio, Tempo One, and no change. I checked voltages on Q1 of the RF board and values are correct on that. I have tried some used 6149 tubes and no change. I did find a pair of NIB 6149A tubes but noted that the cap on one was loose and looks like it has a crack below the cap. When I tried the NIB the one without the crack really glowed, none of the other even the S2001 that are on the radio don't glow like the NIB.

Thats as far as I have gotten. I will proceed with your directions.

Thanks
Carlos

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by Jimmy, WB2KNR.
There were 25 stations checking in under good band conditions.

We had the following number of radios checking in.

2 running TS-520(x)
4 running TS-530(x)
3 running TS-820(x)
5 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

He was running a TS-520 with his SB-200 AMP.

The Sunday net was run by me, WB0IQK. There were
10 stations checking in under poor good
conditions. We had the following number of radios checking in.

1 running TS-520(x)
3 running TS-530(x)
0 running TS-820(x)
1 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940 + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome

as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:

I assume you are measuring DC voltages at Q1 Het Osc FET? If so, why look there?

Could have good DGS voltages on Q1 and have no Het Osc signal at TP-3.

If you can adjust the zero signal (resting plate current) to 60ma in SSB mode then it tells you that you have two of the requirements for ALC indication met. You have 6146 final tube cathode emission and the bias voltage is set somewhere around -55vdc. Now what else do you need?

You need RF drive voltage at the 6146 tubes.You need it at the control grids of the 6146 finals (pin 5).

If you have -55vdc bias voltage then you need a minimum of 39 rms RF volts of drive to just begin to see any ALC indication (39 x 1.414 = 55). For full scale ALC indication you will need around 45 to 47 rms rf volts (47 x 1.414 = 66 peak rf volts). At 47 rms volts the control grids will be sufficiently positive with respect to the cathode on the positive going half of the RF drive envelope to cause ua grid current to flow. When that happens the ALC amp turns on and reduces the ALC bus voltage from it reference level and drives the S-meter up scale.

To measure rf voltages you need one of the following:
1. O-scope (45 x 2.828 = 128 rf volts P-P)
2. RF millivolt meter with 40db attenuator probe
3. VTVM or DMM and RF probe (3 diode version)

Absent a way to measure RF voltage using the TX Level Diagram in the Service Manual you will be just shot gunning once you have tried the simple stuff like another Driver tube.

With the covers off in about 10 seconds you can tell where you are losing RF drive at if you have a means to measure RF signal voltages. Once you see where losing it at then need to make sure you have the "goes ins" and "goes outs" at that stage. If you have that then it is time to look at DC voltages at the involved active devices. Very seldom a bad FET, Transistor or Mosfet.

For example lets assume you have 250mv rms RF volts drive at TP-2 (this is your TIF signal from the IF board) and you have nothing at MD. This is telling you that you have no RF drive voltage at the Drain of Q3 Het Mixer. Next step would be to measure the RF signal level at TP-3 which is the Local Oscillator (LO) for Q3 Transmit Mixer. You should have approx 1.0 RF volts at TP-3. For Q3 TX Mixer to produce RF drive output of approx 2 rms rf volts at its Drain you need two "goes ins" at Q3. You need TIF signal at Gate 2 and you need Het LO at Gate 1.

If you do have good RF drive (TIF signal) at TP-2 and good Het Osc (LO) at TP-3 and no RF voltage or very low at MD then time to look at DGS voltages at Q3. Perhaps you dont have operating bias to the gates.

This is an example of how you troubleshoot.

Terry,
no disrespect but you lost me a bit. Dummy it down a bit for my poor brain.

I am using a Fluke 87 true RMS DMM. I have a scope but have not pulled it out.
I was not sure of what board you meant to check the RMS voltage at. The IF or Osc board.

Mike,
I did voltage measurements at the HV and Rect boards. Here is what I get. In the process I got hit with 800v on my nail and that freaking hurt, my arm went numb for about 30mts. Made contact with the HV board 800v pin.

HV board

Rec Send Tune 125.8 122.5 FSB 264.7 258.4 HV 49.1 49.1 210 265.4 259.4 800 967 967

Carlos:

I am sorry but this is last thing I want to happen to any of our members. Been worried about this since joining this group. Not only dont want anyone to get hurt or killed I dont want to be liable due to them attempting to follow my written directions.

No disrespect to you either. I can only repeat one last time and then turning this over to the others:

If you have no Screen Grid voltage to the Driver tube or sufficiently reduced Screen Grid voltage to the Driver tube then you will have no ALC indication. The Driver tube screen grid voltage is not supplied via R5/R6 divider.

If you have no Screen Grid voltage to the Final Tubes you will still have ALC indication, but no RF output. Loss of ALC indication and Loss of RF drive can have the same root cause or a very different root cause.

Loss of the Tune mode divider resistors has nothing to do with loss of ALC indication. Not sure why others have taken you down that path?

If you report you can peak the Drive control in Tune, but have no Plate current dip and cant load radio in Tune mode then should attempt to load in CW mode and if you can load then screen grid divider resistors is most common root cause for no RF output.

What I understood was that you had no ALC indication while attempting to peak the Drive control with the CAR level pot advanced. If that is your problem measuring Screen grid voltage on the 6146 Final tubes is misguided. Validating that you have Cathode emission, proper operating bias voltage, and proper RF drive is the way to troubleshoot that problem.

All of my previous post was related to the RF board. You need to study the block diagram, schematic, and the TX Level Diagrams.

You are a very very lucky person.

I forgot to comment about your Fluke 87 DMM.

No where in my post did I list a DMM (true rms or otherwise) as a test instrument to measure RF drive levels. Most DMMs can only measure AC at an RF rate up to around 15khz or so. You will be measuring AC at megahertz rate.

The point of my post was to tell you that you normally measure RF signal voltage with one of the three instruments I listed and when you find required signals missing you can then pick up your Fluke DMM and measure DC voltages such as DGS and CBE.

I gave you the Test Points on the RF drive signal path and the expected RF levels at those test points at the TX Mixer on the RF board as a place to start. It is the RF board and not the "Oscillator" board. I gave you the signal levels in rms because that is how they are listed on the TX Level diagram because the TX Level diagrams were developed by KW using a RF VTVM which displays measured voltage in rms.

I also gave you the conversion from rms to peak and peak to peak in the event you would be using an O-scope. If you are going to use a Scope that does not have on screen digital display of RMS voltage level then you will need to convert the RMS levels on the TX Level diagram to P-P. You do that by multiplying the RMS values by 2.828 or simply by 3. So the MD level at output of the TX Mixer will be around 2.0 rms volts which when measured by your Scope will be approx 6 volts Peak to Peak (P-P).

Recognize that any test instrument that you use to measure RF signal voltages in your KW Hybrid will alter the readings due to the input Z of that test instrument. That is why KW specifies very low capacitance probes in the service manual where they listed test equipment needed. It will take some experience to recognize the de-tuning affect of your particular test instruments when taking TX Level Diagram measurements. Very hard to hang a piece of test gear on an LC resonant circuit without detuning it.

When measuring power supply and vacuum tube screen grid and anode voltage you may want to consider down powering, connecting the meter test leads to the test points, then getting yourself in the clear, re-powering and noting the meter indication, then down power and wait for capacitor discharge and disconnect the test jumpers. This will slow you down, but safer method assuming you dont get in contact with alligator or mini-grabber jumpers laying on the bench connecting your DMM test leads to the radio. No shame in using this method especially at the PA cage RF plate choke. Just have to make sure you have very good positive jumper connections that cant pop off during measurements and fly around and make contact shorting something.

Using this medium I have given you all the help I can. Hopefully you have learned a very valuable lesson. Hard way to learn.

Carlos,
The final tubes in all KW hybrid are 2 x "6146B/8298A/S2001A's" not "6149's". The Japanese version of the 6146B/8298A is the S2001A.

The 6149/5703 is a medium-mu subminiture triode used as an oscillator, class C amplifier, or frequency multiplier in the VHF frequency range. The 6149 tube has wire leads. The data sheet for the 6149/5703 is available for viewing/studying at the following link:
http://www.google.com/url?sa=t&rct=j&q=&esrc=s&source=web&cd=1&ved=0CDEQFjAAahUKEwi1o6Sh5pHGAhVUjpIKHYWZA3Q&url=http%3A%2F%2Ffrank.pocnet.net%2Fsheets%2F127%2F5%2F5703.pdf&ei=SNJ-VbXfF9ScygSFs46gBw&usg=AFQjCNFbNxNfGYMPEqk7EVQphpcfsmRlRA&bvm=bv.95515949,d.aWw&cad=rja

The picture below shows a 6149/5703 subminiture triode with it's wire leads.

The 6146B/8298A/S2001A is a Beam Power Tetrode used in the KW hybrids as the final Class AB1 RF amplifier. The data sheet for the RCA 6146B/8298A can be found at the following link:

A related question, 6146A, B or W. What are the pluses and minus?I’m getting between 80 and 90 watts into a dummy load depending on the band. Is my 520 telling me it’s time to replace some or all of the tubes? GaryAA7YO
The TS-520's normal DC input power is 160 watts. The typical maximum final amplifier efficiency is 60%.
The following is an example.

Let's assume the 520's HV is 795VDC and the IP is 200ma, keyed into your 50 ohm dummy load in CW mode.
Multiply .2 x 795 will give you the DC input power

.2 x 795 = 159
Now multiply the DC input power by .6 to get the approximate power that will be present at the antenna socket
.6 x 159 = 95.4 watts
If your watt meter is an average watt meter, in sideband with ALC peaking within the ALC scale, you will see approximately 20 to 25 watts peak on the average watt meter. Do NOT turn up the MIC gain for higher power output, all you will do is cause splatter and intentional interference to adjacent frequencies..

Based on your power output levels, there's no need to buy / replace the driver and final tubes in your TS-520. If you ever have to replace the final tube, do NOT be hood winked into buying matched tubes!!!.

Terry,
That is what I am doing now. Power down, clip on, power up, measure and power down.

Now that makes more sense to me Terry, that I can understand and follow. Will get the data probably need to pull out the scope out. It may very well be the drive tube that is bad. Unfortunately the driver tube is not one of the tubes that I found in the box of tubes from the SK estate. This radio sat idle for about 20yrs in the radio shack without being powered up.

Please don't let my ignorance of some things be a reason for not commenting on my post, I value your experience and knowledge. That is why I can to this user group.

There are numerous web pages on the differences between the tubes. They are mostly minor. See http://ab1vl.com/kenwood-ts-530s/the-6146b-story-fact-and-opinion/ for an outline. Agreed that matched tubes is a scam to divest honest hams from their money.

Carlos:
Nobody is going to point and laugh. If they put up with me, you are not even on the radar screen for ridicule. This is probably THE most helpful and friendly group of enthusiasts you will ever find. Yes, there are some sour individuals in the group. NO, they don't carry a lot of weight with the rest of us.

If Terry, Mike, Joe, or one of the other very experienced hands is trying to help you, if you will keep trying what they ask you to do, you will almost certainly get your Kenwood transceiver in like-new condition. AND you will wonder why you bothered with anything else before you are done.

These machines are not "Cadillac" quality. They are the Rolls-Royce of HF ham equipment, and this group is the equivalent of the Manhattan Project for knowledge about them. It doesn't get any better than this.

Dig into the old messages archived (POORLY, sorry) at the yahoo.com nightmare of a web site. Almost anything you need or encounter will be in there somewhere. It might be hard to find (which is NOT due to the people on this list, but to the profit-hungry idiots at Yahoo), but once you get the hang of things the breadth and depth of the knowledge in those archives is almost indispensable to anyone with one of these radios.

Look into old posts regarding the correct equipment for troubleshooting and measuring hybrid circuits. Pay extra attention to the parts where we all keep saying to NOT GET ACROSS THE HIGH VOLTAGE sUPPLY !!!! You can DIE if you take this amount of current across your chest cavity. NO I am not being overly cautious here. Your radio can kill you. Take this as gold-plated GOSPEL from someone who has been zapped so many times he can probably spit sparks. (Only needed the defibrillator ONCE. So far.....)

You MUST get a meter with at the very LEAST

TEN MEGOHMS (1x10^6 ohms) INPUT IMPEDANCE.

More is better. Most cost-effective would be an old "Vacuum Tube Volt Meter"- or "VTVM." Heathkit company made several models, most any of which will do the job just fine. There are solid-state volt-meters, usually very hard to find and quite expensive, with higher input

impedances (100 megohms and more - 1x10^8 ohms), and if you can get one of them it would be even better.

(If you don't understand why the input impedance makes a difference, contact me off of the yahoo list and I will try to explain it to you.)

An oscilloscope with the correct probes will do about as well as a VTVM, if you know how to interpret the readings you get from it. (Also contact someone, me or one of the other members, if you do not understand. Some of us can even deal with languages other than English, if that would help you.)

Keep trying, and someone here will try to help you get your Kenwood instrument working as best it can. Parts resources, troubleshooting, operation tips, whatever you need. We (as a group) will do our level best to help you.

Keep the faith. It will all work before we are finished.

Carlos:

OK much better to go to "extremes" when it comes to personal safe work practices.

Very easy to get too complacent working around transmitters and linear amps.

I always put the PA cage cover back on and secure it with 1 screw during repair and troubleshooting. I have been guilty of flipping the chassis over multiple times with rig powered and PA cage cover removed. Not a good practice.

I also have cardboard and plexiglas barriers of couple of sizes that I can lean over or cover the HV filter cap and HV rectifier board area when working on energized bottom of the rig. That way I cant accidentally touch or have a test lead swing into or drop a tool into the 900vdc or 300 or 210 supplies. For example when I am lowering the CAR Osc module on a TS-820 and it is swinging in the breeze I use a barrier to cover the HV filter caps so I cannot swing the metal can into it or the temporary ground clip make contact.

Have to remember also depending on the radio that 300 and 210 is available for contact at remote locations like filter caps, IF board, RF boards, molex connectors etc. For example on the TS830 you can go to measure AGC bus (3.6vdc) at molex connector on the IF board and on same connector just one pin away is 340vdc. Easy to get turned around and get a nasty surprise.

In order to be safe you have to be aware of the as-built configuration of your model radio. If you dont know where the rattlesnakes are at then hard to be on your guard. Of course best policy is to never make any bare hand contact without taking a contact voltage measurement with a known good voltmeter. That one step keeps electricians alive everyday. Also never want to take short cuts. I have to admit that I have to remind myself of that. I know where the rattlesnakes are at and the safe work practices to handle them. Just have to make sure I am religious about it.

Terry,

This is great advice. I'm going to pick up the practice of covering the HV filter caps and rectifier boards when working underneath or in situations where I might contact accidentally with a tool or loose test lead. I always keep one hand in my pocket as well!

I just saw an announcement about the WVa ham who tragically became SK after being electrocuted working on an antenna. These are sobering realities.

Thanks for the reminders to us all.

Dave

Carlos:

OK much better to go to "extremes" when it comes to personal safe work practices.

Very easy to get too complacent working around transmitters and linear amps.

I always put the PA cage cover back on and secure it with 1 screw during repair and troubleshooting. I have been guilty of flipping the chassis over multiple times with rig powered and PA cage cover removed. Not a good practice.

I also have cardboard and plexiglas barriers of couple of sizes that I can lean over or cover the HV filter cap and HV rectifier board area when working on energized bottom of the rig. That way I cant accidentally touch or have a test lead swing into or drop a tool into the 900vdc or 300 or 210 supplies. For example when I am lowering the CAR Osc module on a TS-820 and it is swinging in the breeze I use a barrier to cover the HV filter caps so I cannot swing the metal can into it or the temporary ground clip make contact.

Have to remember also depending on the radio that 300 and 210 is available for contact at remote locations like filter caps, IF board, RF boards, molex connectors etc. For example on the TS830 you can go to measure AGC bus (3.6vdc) at molex connector on the IF board and on same connector just one

pin away is 340vdc. Easy to get turned around and get a nasty surprise.

In order to be safe you have to be aware of the as-built configuration of your model radio. If you dont know where the rattlesnakes are at then hard to be on your guard. Of course best policy is to never make any bare hand contact without taking a contact voltage measurement with a known good voltmeter. That one step keeps electricians alive everyday. Also never want to take short cuts. I have to admit that I have to remind myself of that. I know where the rattlesnakes are at and the safe work practices to handle them. Just have to make sure I am religious about it.

You can also study the following GE 6146A and RCA 6146B/8298A tube data sheets.

6146A
http://w5rkl.com/wp-content/uploads/2014/04/6146A-GE.pdf
The 6146 is the same tube as the 6146A except the 6146A has a more rugged filament.

The Japanese S2001 is the same as a 6146A.

6146B/8298Ahttp://w5rkl.com/wp-content/uploads/2014/04/6146B-RCA.pdf
The Japanese S2001A is the same as a 6146B/8298A.
6293 Pulse-rated 6146
http://w5rkl.com/wp-content/uploads/2014/04/6293-pulse-rated-6146A.pdf

Don't expect higher power output by simply replacing the 6146B/8298As with the 6293, it won't happen.
There is very little inter-electrode capacitance difference between the 6146/6164A (.24pf grid #1 to plate in the 6146/6146A) and 6146B/8298A (.24pf grid #1 to plate in the 6146B/8298A).

The 6146B/8298A has a higher plate dissipation than the 6146/6146A and there is a 125ma difference in the filament current at 6.3VAC. Other than those differences, the tubes are the same.

> A related question, 6146A, B or W. What are the pluses and minus?I’m getting between 80 and 90 watts into a dummy load depending on the band. Is my 520 telling me it’s time to replace some or all of the tubes? GaryAA7YO
> The TS-520's normal DC input power is 160 watts. The typical maximum final amplifier efficiency is 60%.
> The following is an example.
>
> Let's assume the 520's HV is 795VDC and the IP is 200ma, keyed into your 50 ohm dummy load in CW mode.
> Multiply .2 x 795 will give you the DC input power

.2 x 795 = 159
Now multiply the DC input power by .6 to get the approximate power that will be present at the antenna socket
.6 x 159 = 95.4 watts
If your watt meter is an average watt meter, in sideband with ALC peaking within the ALC scale, you will see approximately 20 to 25 watts peak on the average watt meter. Do NOT turn up the MIC gain for higher power output, all you will do is cause splatter and intentional interference to adjacent frequencies..

Based on your power output levels, there's no need to buy / replace the driver and final tubes in your TS-520. If you ever have to replace the final tube, do NOT be hood winked into buying matched tubes!!!.

Hi Dave;

I worked for nearly 40 years in the electric utility industry and unfortunately have been involved up close and personal with more than one electrical fatality. This included in house electricians, contract electricians, tree trimmers, and overhead line men (4kv, 13.8kv, and 19.9kv are not very forgiving).

I know people preach the hand in pocket method, but it isnt always practical and most industrial electricians dont practice it for variety of reasons. One it can put you in an unbalanced condition. Often the free hand is used to change meter ranges or handle the flashlite. I understand the concept of not wanting hand to hand current thru the heart. If it works for you that is fine.

Absolute best work practice is to never bare hand touch anything until you perform a "live-dead-live" contact voltmeter test. Never use a proximity tester (glow tube or tic-tracer as most do not detect DC). Always employ a real voltmeter. Of course in industrial electrical world also would work under red tag or lock out clearance and the standard is that nothing is dead unless de-energized and verified de-enerigized and grounded.

Have to be very careful defeating interlocks. Sometimes cannot be avoided. More likely to run into them with high power linear amps.

We also employed a variety of protective gear including nomex flash coats, face shields, and various rubber insulating gear.

Always good to remind ourselves from time to time about the flash and shock hazards and the safe work practices to manage the risks.

Thanks
Terry K9TW

Thanks for the support from everyone.

I used to work for a wire and cable company many moons ago as a failure analyst and I can't think of the number of times I got hit with hypot testers at 20Kv dc low current, megohmmeter, chainbead spark testers and the like. Some left me felling more goofy then normal. Yeah the cage is back on and I pulled out 1/4 inch plexi that I now tape over the HV and transformer area.

I gave the VTVM away before I knew what it was for, I just have to ask Skip for it so I can get to the nitty gritty of the transmit problem.

Now to find time after work. Lets see how tomorrow plays out.

Lou:

Very good point. Far too many cowboys in the industry and in many cases not completely their fault. Everyone at end of day should go home exactly as they came to work.

Everyone who works in maintenance arena of any type faces risks every day. Falls, rotating machinery, high pressure and high temperature, burns, shocks, being crushed etc. Maintenance is about recognition of safety risks and employing personal protection and safe work practices to manage the risks and of course must also protect any transient traffic at the job site.

Small companies are very poor at pre-job briefings where safety is the primary discussion. I use to ask my senior people to brief me so that I could be 100% certain they understood the risks and what they planned to do to manage it. Of course then the boss has to be in the field to practice performance management and provide recognition and coaching and discipline if needed.

I have been involved in more than one accident investigation and it was very maddening when co-workers would say things like " oh yeah not surprised" or" Joe was a cowboy" or "I never liked working with him". I asked who did you tell? Well you dont narc. Shame on them. Of course 1st line supervision has some responsibility here as you cant know what is happening in the field from behind your desk.

I once took over a shop where burned off screw driver tips in the tool pouch was a badge of honor and senior electrician told the new kid when taking voltage measurements to ground his elbow on the cabinet so when you get shocked it wont go thru your heart! As I was working to change that culture had a senior electrician tell me that " If you work in the industry it isnt a matter of IF but WHEN!" and "You just cant help but have some shocks and flashes". I told him if he really believed that then he should run to parking lot and get in his car and go home. This was a shop that had lots of safety slogans and posters and safety meetings and senior management was proud if its safety program. They just didnt have a safety culture. No one had internalized and practiced it.

Worse thing any manager has to do is go tell a family that their husband, wife, father, mother, brother or sister isnt coming home or is coming home very different. Glad I am retired and only responsible for my own personal safety.

Attachments: 1 described; binary payloads are missing from this source WARC

I have an excess to my needs Heathkit IM-17 all solid state AC/DC/Ohms meter (I have 2 but only need 1). The meter is in excellent condition, works great, and has the stock probes.

The following link contains a QST write up on the IM-17, containing specifications.

http://www.google.com/url?sa=t&rct=j&q=&esrc=s&source=web&cd=4&ved=0CE0QFjADahUKEwjimsTZnpTGAhWGooAKHYhYANo&url=http%3A%2F%2Fwww.nostalgickitscentral.com%2Fheath%2F73-index%2Farticles%2FIM-17-8-68.pdf&ei=5hmAVeKPDYbFggSIsYHQDQ&usg=AFQjCNH5mg6Gr9CY4uuJpAGfiBBAr1nHEg&bvm=bv.96041959,d.eXY&cad=rja

I perform the manual's calibration and replaced the batteries (8.4VDC and a single C cell).

A copy of the complete assembly manual including parts list and schematic in pdf format will be provided to the buyer via email.

The probes are hardwired to the meter (not a modification but factory design). The meter face is perfect and the clear cover has no scraps or cracks and there are no dents or scraps on the front panel. The controls and rotary switch (Ohms, DC, AC select switch) function properly and have been thoroughly cleaned. The meter requires 2 batteries, an 8.4VDC and a C cell. I will include a new in sealed packaging, spare 8.4 volt Duracell Procell DA146G battery.

The one and only problem is the top cover snap is worn requiring a wire wrapped around the handle to keep the lid closed when the meter is not in use.

The picture below shows the IM-17 you will get.

I'm asking $35 plus shipping.

If interested contact me off group my call at yahoo dot com

Hi folks,

my TS-830 works very fine now. However, from time to time I find some interesting things. When tuning in the 40m band (usually around 7.100 MHz) I see a very high initial plate current. I tune like this:

* turn LOAD fully ccw
* turn PLATE to to "7" area
* listen and turn DRIVE to noise max
* MODE to "TUNE", METER to "ALC"
* switch to SEND (into dummy load) and adjust DRIVE to max. ALC
* METER to "Ip", switch to SEND and dip plate
* MODE to CW-N, flip SEND and see 280-300mA Ip (LOAD still fully CCW)
* turning "LOAD" only rises Ip (I try this for 1-2s only...)

To bring the Ip down to normal values I have to detune PLATE. Output while doing this is 120-130W at the AT-230.

All other bands are normal in this (LOAD fully CCW is < 180mA usually)

I can live with that, but is this normal?

73,

Martin DB2MJ

Martin,

You did not specify what position you have the "CAR" control set to?

Can you reduce the transmitter's high IP indication on 40 meters in CW mode by rotating the CAR control CCW?

You left out this part:
Switch the meter to power and peak the output.

"Dipping the plate" to me is unnecessary. If you set the plate control in the correct sector of the band, and then go to the meter's power setting, and then just peak it using both controls. Once its peaked I move the load control slightly more CW to see a slight power drop. (All this is done in a second or two)
Once I have peaked the power, THEN I go to Ip to see how much current the tubes are drawing as the final check.

Thanks for the hint, Mike. Usually I don't set CAR to a special value,
if I can peak DRIVE somewhere on the scale, that's ok. If I used the 10m
or 15m band previously, the CAR pot will be in a high position (these
bands need more CAR for peaking DRIVE). That could be the reason,
usually I switch bands from 20m (my usual hangout) to 15m, 10m and then
40m. This leads to a fairly high CAR position, 10m needs lot of drive.

If you are getting full plate current with the plates of the Load capacitor meshed and the Tank dipped to resonance you may have a bad 40 meter padder capacitor (C13) on the S22-3 deck or a bad contact on the switch (inside the PA cage). Sounds like you immediately have too little capacitance in shunt with the SO-239 which means too much Xc and max RF current is being transferred to the RL branch.

You can try temporarily tacking a 270pf cap across the Plate Load cap to chassis ground to see if you now can open the Load cap plates as normal to begin transfer of RF current. Should be a Class 1 cap, but for short testing can use a Class 2. If you cant get it across the Plate Load cap inside the PA cage then install a coax Tee and tack the cap across a PL-259 and screw that on the open Tee.

Further to Terry's comment. If you find that it is the padder capacitors, this is a fairly simple fix. Email me directly and I can help you with it, very straight forward, but must use correct Type 1 capacitors.

Martin:

No disrespect intended, but I would not use the CAR Level Pot in the loading process in any other manner than what is described in the Operating Instruction Manual. It is used to peak the drive and when done properly loading in CW mode it can be used to set the RF output level lower than 100 watts if desired. No where in the loading procedure do they tell you to reduce Ip with the CAR LEVEL POT anytime during the loading procedure when you exceed max Ip (either actual or self imposed limits).

I have seen in person at my bench an owner grab the CAR Level pot during loading when they saw that the plate current exceeded 225ma. I was not too quick to recognize what I just saw and then have any meaningful dialogue as to why this was done. It is unnecessary and misguided. I have also seen it taught in some You Tube videos.

The CAR Level pot controls the TIF signal level and ultimately the RF drive level to the Control Grids of the 6146 finals. You always want to load with maximum RF drive voltage to the Finals. Loading with reduced RF drive can result in the Plate load capacitor plates being too far meshed ie the tank Under Coupled. If anything you want to be slightly Over Coupled when done loading. That means the Plate load cap plates open slightly (less capacitance). This establishes the proper relationship of RF voltage and RF current in the Tank for the antenna impedance that is being presented to the tubes. If too far Under Coupled a good way to have RF voltage arc overs in the Tank especially across the Plate Load capacitor. Better to have a little too much plate current as potential damage wont be acute.

I dont think you have a loading error here. Almost always when you have high plate current with the Plate Load capacitor plates fully meshed on any of the three lower bands it is a clue that you have a problem with fixed padder caps.

Could be wrong. I have been more than once!

Terry K9TW

These days, only SMD devices are easily available with C0G dielectric and >=500V. I already used several SMD caps on the final board of my TS-830S when wired caps are unavailable (easy, they fit exactly between the copper traces on the board, just remove the protective laquer and solder them in). However, this cap will be hanging free inside the cage. Is it advisable to solder two wires on the SMD cap and use it to replace the original wired cap? Farnell has C0G 270pf/500V caps for a few cents (10 for less than 3?)...

I have a typo.

Too much Capacitance means too little Xc and not too much Xc as I typed.

The way the Plate Load cap works is it is in parallel with the load. Same as two resistors in parallel.

With its plates fully meshed the capacitance is high which means you have low Xc in parallel with antenna impedance. This means that most of the RF circ current in the Tank is flowing thru the Plate load cap and very little RF current in the antenna load or parallel leg.

As you begin the loading process by unmeshing the plates the capacitance goes down and the Xc goes up and now RF circ current begins to flow heavier in the Antenna load branch of this parallel circuit.

Sorry about that.

Terry, thanks for the interesting point you just made. I re-read the manual and it states "...Peak the DRIVE control. If the meter pegs or goes out of the ALC range, reduce the CARRIER control for an on-scale reading [...]".

Obviously I understood this wrong. The "on-scale" means the ALC sector (at the left half of the instrument) and not "if the needle has room left to the right, peak it". I'll try it with proper adjustment of CAR and be back.

I can read your post if I view the "Source".

KW added this change to operating manual instructions to keep the peak indication inside the printed ALC scale with the TS830 model as nearly every new owner of any KW hybrid when peaking the Drive Control in Tune mode had that same question. "What does an on-scale reading mean"? "Does it mean panel meter FSD or ALC scale FSD?"

The truth is none of the meter scales mean anything when peaking the Drive Control in TUNE mode on any of the KW hybrid models. I have explained that until the cows came home and it just wont die.

You are simply tuning band specific LC circuits in the Mixer and Drive coil pack to resonance at the VFO setting so that you have maximum RF voltage swing at the control grids of the 6146 finals. You are not setting a grid current or RF voltage level. If you peak within the black printed scale you will see approx 35 to 40 ua (micro-amperes) of 6146 grid current and if you peak near the panel meter FSD (350 ma for example) you will see approx 45ua of 6146 grid current. These are values that I have measured and not what I believe. May be slightly less on the TS520 and TS20S (around 30ua). MEANINGLESS.

The only time you need to use the black ALC scale is when modulating the radio in SSB mode so that you dont risk splattering on adjacent frequencies.

If it makes you happy or comfortable to peak the Drive indication within the ALC scale have a ball. Probably a good practice for new folks or appliance operators from a human factoring perspective. Just never use the Drive control as a level control. I have seen that more than once.

In connection with the padder capacitor (C13; 270 pf @ 500V)- would a silver mica capacitor be suitable as a replacement, rather than a Class 1 ceramic? I confess to being rather ignorant about the relative merits of one capacitor type vs another.

Yes Silver Micas have relatively low Temp Coefficient (they are Positive and not NPO or negative) biggest problem is physical size. In the Hybrids they are under the Plate Load cap or between the end of it and the tank coil so not much room. They are installed like a stack of dimes that have been slipped over each other.

Today hard to find NPOs but can find COGs, but often find them in low PF values and not the higher values that we need.

These ceramic npo caps are available. But are not cheap, last batch I bought were over 1.95 each, but could only get in 2 & 3 kV. These 3 caps usually fail or are out of spec due to proximity of 6146 valve, I am now seeing more and more cracked or charred and out of spec Excessive length of time tuning in cw out of resonance doesn't help either. Shouldn't take more than 5 -10 secs to tune in cw

Question:
What voltage should I be getting on the 2 HV capacitors, C19 and 20?

With the radio upside down, panel facing me. On the left cap, left ping I get 960vdc, the right pin I get 481vdc.
Right cap, left pin I get 482vdc, right pin I get 0 volts.

These caps are wired in series, your measurements are exactly correct
(481 * 2 = 960 incl. measuring err).

Carlos,

The picture blow is a simple drawing showing a schematic of a voltage doubling power supply. The HV supply in the KW hybrids is the same. "RL" in the picture is the "Resistive Load" connected to the voltage doubling supply's output (the final amplifier stage when the final tubes are conducting in the case of the KW hybrids).

The KW Hybrid HV power supply is the same as the above "voltage doubling" supply. The only components missing in the above picture are the two 470K 1/2 watt resistors connected across each capacitor as used in the KW hybrids. The 470K 1/2 watt resistor act as equalizing resistors to equalize the voltage across each capacitor and as bleeder resistors when power is turned OFF.

The voltage doubling supply works as follows:

During the positive half of the power transformer's HV secondary winding AC sine wave voltage cycle, capacitor "C1" charges. During the negative half of the power transformer's HV secondary winding AC sine wave voltage cycle, capacitor "C2" charges. At the end of the charging cycle of C2, the power supply discharges as though there is "one 60ufd" capacitor. The charging process repeats itself as long as power is applied. This is the simple explanation, a more in depth explanation can be found in the ARRL handbook chapter that covers power supplies which I recommend you spend time studying.

If you connect your DC volt meter, RED lead to C1's "+" lead and BLACK lead to C1's "-" lead, the DC voltage will approximately 1/2 of the supply's output voltage. Move the RED lead to C2's "+" lead and the BLACK lead to C2's "-" lead and you should see approximately the same DC voltage. Add the 2 DC voltages you measured together and you should see the "doubled" voltage output of the power supply.

I must say and I don't care how long you or anyone reading this has worked with voltages, AC or DC, I can't stress enough the importance to use extreme caution and pay attention when performing these voltage measurements!!! The DC voltage in the KW hybrid can easily "KILL YOU"!!!

The following explains how to calculate total capacitance with capacitor's wired in series.

The total capacitance of the KW hybrid HV supply, both capacitors connected in series, is 60ufd with an approximate DC working voltage of 1KV. I calculated the total capacitance of the two capacitors wired in series, use the following formula:

C1 x C2 / C1 + C2 = Ct

The formula used to calculate more than 2 capacitors wired in series is as follows:

Ct = 1 / 1/C1 + 1/C2 + 1/C3 and so on.

Here's an example of three 125ufd 450VDC capacitors wired in series. The total capacitance is found using the above formula with the values substituted shown below:

1 / 1/125 + 1/125 + 1/125 = Ct

.008 + .008 + .008 = .024 (NOT Ct just yet)

1 /.024 = 41.666 ufd at approximately +1350VDC (Ct)

The capacitor's WV (Working Voltage) for capacitors in series, is "added together" (450 x 3 = 1350).

Capacitors wired in "parallel" simple "add" their values but the voltage rating does NOT add, the voltage rating is the same as the rating printed on each capacitor. For example, if three 125ufd capacitor, 2 of which have a voltage rating of 350VDC and one has a voltage rating of 450VDC, the total capacitance "125 + 125 + 125 = 375ufd" but the maximum WV that can be applied to the 3 capacitors should not exceed 350VDC!! Why not 450VDC? Because the same voltage is applied to each capacitor connected in parallel. The maximum voltage that can be safely applied to the three parallel connected capacitors stated above is /*ALWAYS*/ no higher than the /*LOWEST VOLTA*//*GE RATED CAPACITOR*/ in the parallel connection!!!

I forgot to include the following.

The formula to calculate the approximate voltage across each series
connected capacitors is as follows:

Cv = Vs x Ct / Cx

Cv is the approximate voltage found across each series capacitor
Vs is the source voltage
Ct is the total capacitance of the series connected capacitors
Cx is the individual capacitor's value

Understanding and using this formula can help one be able to calculate
the voltage that will be applied across each capacitors wired in series.
This is especially important when connecting capacitors in series that
have different WV (Working Voltage) ratings. "WV" is the voltage rating
stamped on the side of the capacitor.

Mike,
This is very helpful stuff-thanks. Brings up question I've been thinking about. I just re-capped a couple radios, one with a "re-cap kit" for the HV that had higher capacitance than the original 100 uF 500 VDC units. Why do the kits offer 120, 150, or even 180 uF? They say it helps prevent "voltage sag" under load. If so, why didn't the designers use a higher value? Economy?

Developers had to use what they could afford to spend and fit into
existing room, so capacities of large HV caps tended to be on the lower
end of the usable range. These caps had capacities ranging from -20% to
+80%, so you can replace the 100uF types with everything from 100 to 180yF.

These days, electrolytic caps are much smaller and cheaper than 35 years
ago. The sellers of these HV kits are looking for caps with 35mm
diameter to fit into the existing clamps. There are no 100uF/ types on
the market with 35mm... no problem to get them with 30mm or 25mm
diameter. Thats why at least one seller offers new clamps to mount the
smaller types in the hybrids.

Mike,
Great information and explanation. I measured each cap and sure enough they are about 480 each. So I know they don't have to be replaced.

Carlos,
Mike-w5rkl does a great tutorial.....you too Terry(k9tw)

Your voltages are just fine, but when you get the rig fully up and running, measure the voltage sag under full output...you should see no more than about 10-12% voltage drop. Many here do not advocate the "replace it cause it's old" school of thought...but with the HV caps, that's a bit of a different story. When one or both HV caps fail...more likley just one will...the results can be catastrophic. I replace them...cheap insurance.
Continue your rebuild, and keep us posted...so others in the future(or present) may benefit.

No you do not know that!
What do the rupture vents look like?

Vents can be raised, swollen, bulged and/or cracked or combination. When you see them bulged and cracked it is time to replace. Only matter of time before they will fail and when they do can cause collateral damage. Cleaning up the mess that they spew out is least of problem. Can take out the HV rectifier diodes.

Also need to look at ripple and ESR test as well as look at the regulation (sag) on the doubler under load.

I dont recommend that you attempt to measure the ripple. Requires proper scope probe.

David,

I assume the "voltage sag" you are referring to David is when the 6146 plate HV drops from say +920VDC in standby to say +875VDC in transmit. That is NOT a "voltage sag" but rather a "normal voltage drop" (IR drop) that occurs in the 6146 plate circuit when current flows in the plate circuit.

I have videos on my website where I discuss voltage drops. You might want to view them so you will understand how voltage drops occurs.

Dave:

KW used a voltage doubler as most other manufacturers did to save money. Transformers are large and take up room, heavy, and expensive. The HV supply sees intermittent duty so they chose to use capacitors to help supply the load current. That way can use a transformer with half the copper winding. It is true voltage doubler supply can only handle low current loads and does not have very good regulation. Today would be used in microwave ovens, bug zappers, ozone generators etc.

The benefit of increasing the capacitance value from the stock capacitors is probably as much about reducing ripple voltage as it is about reducing voltage sag on the capacitors. How much ripple can you stand in a 900vdc anode supply for a Class AB-1 Linear RF amplifier?

With the original 100uf caps in series you have total capacitance of 50uf (disregarding tolerance). At 120 hz the caps are being topped off every 8.3 msec. So the voltage on the caps in between charges does "droop" or "sag" as the capacitors supply the load current. Assuming 250ma load current 50uf of capacitance will result in approx 10 volts of ripple. Of course never see that much steady state load current in SSB or CW mode.

If you install two 150uf caps for total of 75uf the ripple will be reduced to approx 7 volts.

I suspect all the folks supplying caps today havent thought much about better regulation or reduced ripple. I think they just are supplying what package is readily available.

Martin,
Thanks. That makes perfect sense. The 820 kit came with clamps and were 32 mm, I think. The last two I did were Yaesu FT-901DM's with the HV caps mounted on a separate PCB, so lead spacing was the only critical factor. I put 30mm 100uF units on the most recent--worked fine and lots of space left over.

Terry,
Thanks for the very clear explanation of ripple/"sag"--most helpful. When I ordered my own caps I specified those with the lowest ripple current rating, sometimes referred to as "low impedance" units but I don't know if that helps beyond the basic physics of charge/discharge rate. At that point, I'm starting to exceed my "pay grade.". They seem to work fine and voltages look good. I always also replace the divider/balancing resistors as well. These are almost always out of spec high (megohms vs say 470k) which is a little scary for bleed purposes.

Dave:

If you look at Bill Orrs handbook and ARRL handbooks under what they call design of IVS (intermittent voice service) power supplies you will find nomographs of how to select minimum filter capacitor values for design goal of 5% regulation. I have seen some other texts that say for Linear Amplifier service should design for 3% regulation. Poor regulation can effect CW keying waveform and SSB intermod.

SSB and CW duty cycle results in a large peak to average load current. You need to calculate the Final tube RL just like you would for selecting Pi-network components. Once you get the RL you can go to the nomograph and see the capacitance value that you need.

Approx RL calc is Eb/1.6 x Ip Since it is not easy to determine the the dynamic Eb and Ip under CW keying or SSB speech modulation you have to use the key down plate voltage and current. If we say that it is 825vdc and 225ma then:

RL = 825/ 1.6 x .225 = 2300 ohms. 2500 ohms on the nomograph provides filter capacitance requirement of approx 60uf. That is pretty close to the nominal 50uf that KW gave us with the original two caps in series.

I have been installing a pair of 150uf Nichicon (GN) series caps for quite sometime as they are same OD and use the same clamp rings. I prefer that to the smaller ID caps supplied by some whose clamp ring bolt centers is smaller. I dont want to have to drill holes in the chassis deck. Have a TS530 here now that has set of the smaller id caps installed and only using one of the two mounting bolts on each clamp.

Yes I dont understand why these fellows sell these kits. Perhaps they have cheap supply source and it is pure profit motive?

Perhaps they dont really work on KW hybrids or they work on them and dont mind cobbling them? Sometimes I wonder if the customer really knows what they are getting?

I always try to go back close to design values and configuration. I am not a fan of drilling holes or using glue!

Dave:

I forgot to mention if interested in more study in addition to the handbooks go to Tom Rauch W8JI site as he has good info on transformers, losses, VA rating, etc. Here is quote from Tom.

How much capacitance do I need on the HV supply?
First you need enough capacitance to eliminate any appreciable hum modulation of the output signal due to ripple on the HV. Second, although you may have enough capacitance to prevent noticeable hum from the power supply, you may still wish to add capacitance to improve the dynamic regulation of the supply. Improving the dynamic regulation will improve the linearity of the amplifier and can yield higher peak power output because the voltage doesn't sag as much on voice peaks.

Here is response from Tom W8JI to the above:

"Actually the ESR of the AC source, the load resistance, and the rectifier type determine the ripple and dynamic regulation.

The higher the transformer ESR (equivalent secondary resistance), the less important capacitor size is for anything. This is because the supply starts to act like a R/C filter with the R distributed throughout the AC system feeding the rectifier.

There will be a point where going beyond a certain capacitance does nothing at all. That point is very low with a high resistance transformer.

At 2000V and 500 mA with a transformer ESR of 200 ohms 25uF is acceptable

At the same voltage and current with a transformer ESR of 20 ohms values up to 250uF would continue to reduce ripple. “

Tom doesnt discuss it here, but transformers are speced and designed and wound based on what kind of load they will see. Ones built for purely resistive load will have different ESR/Volt than ones built for high power factor loads. KW selected the HV power supply components to work in concert with each other. Of course production cost is a factor and usually some improvements can be made if you know what you are doing, but often they are marginal and not detectable by human ear and for most of us easy to muck it up making component value changes because we dont have the formal training or experience of a design engineer like Tom. Some folks dont appreciate Tom due to his edgy or forthright delivery, but I think looking past that he is a very valuable resource.

Hi friends.
My TS820S had problems with the digital display, as you have already seen in previous submissions. Thanks to your help I thought that had solved, but now it has happened again. From time to time, they change the digits at random. Nine appears instead of seven or four disappear from 1 to 7, finally, it seems that this crazy.
Following your instructions and others that I found online, I have reviewed the connection of the PCB module DG-1 with mass, I put soldered wires between the two sides of the PCB, I cleaned the molex connectors, both the interconnection of the two PCB as all others, have even re-soldered connectors, but it seems that the problem is elsewhere.
I checked the tension in the 5V-AVR, X43-1220-00 unit and the voltmeter reads 4.96 V. He inspected with a magnifying glass X43-1090-02 rectifier unit, and I see nothing strange. Also, often it happens that when takes time on, changes to work well and usually stay so long.
In short, which can no longer be the problem, so I ask a little help.
Any suggestions are welcome.
Best regards.
Rafa. EA5TV

Hello Rafa,

I have had similar problems with two TS-820S and the only way to solve it was to resolder ALL the counter circuit. Perhaps you have done it already but, if not, the two PCBs inside the metal cage should be disassembled and CAREFULLY resoldered, all the pins, one by one. It is a tedious work, but worth the time.

Terry,
This is really helping my understanding of HV power supply function. I'll check out Tom's stuff as well. The holistic view of overall PS design and function explains a lot about component selection and the (relatively minor) differences we see in various PS designs feeding similar 6146-based PA's.

>
> First you need enough capacitance to eliminate any appreciable hum modulation of the output signal due to ripple on the HV. Second, although you may have enough capacitance to prevent noticeable hum from the power supply, you may still wish to add capacitance to improve the dynamic regulation of the supply. Improving the dynamic regulation will improve the linearity of the amplifier and can yield higher peak power output because the voltage doesn't sag as much on voice peaks.

> At the same voltage and current with a transformer ESR of 20 ohms values up to 250uF would continue to reduce ripple. “
>
> Tom doesnt discuss it here, but transformers are speced and designed and wound based on what kind of load they will see. Ones built for purely resistive load will have different ESR/Volt than ones built for high power factor loads. KW selected the HV power supply components to work in concert with each other. Of course production cost is a factor and usually some improvements can be made if you know what you are doing, but often they are marginal and not detectable by human ear and for most of us easy to muck it up making component value changes because we dont have the formal training or experience of a design engineer like Tom. Some folks dont appreciate Tom due to his edgy or forthright delivery, but I think looking past that he is a very valuable resource.

NO-- but sometimes used interchangeably in engineering text when studying equivalent circuits of transformers.

Rs or transformer equivalent secondary resistance (ESR) isnt something you are going to measure with your ohm meter. If you look at the equivalent circuit you will see primary winding resistance R and series inductance Xl and R and Xl series combo on the secondary side. Rs is the effective resistance and half comes from the resistance in the secondary and the other half is reflected from the primary winding based on impedance ratio. Rs = Rsec + N squared Rpri.

Go to Toms site and search under Boat Anchor and you will see his design of a 6146 Class C transmitter and its power supply (has anode voltage, SG voltage, and bias voltage outputs). He calculates the 6146 tubes Rp and does a load pull on the supply from about 6 watts to 180 watts and you can see the supply voltage %sag for the various amounts of transformer ESR.

Not many transformer texts that I have seen speak in terms of Equivalent Secondary Resistance.

Rafa,
I had the same experience as Jose with my DG-1 unit and nearly all problems were resolved my re-soldering every solder joint on both boards. Unfortunately, even then I had a remaining problem with the counter showing "15.xxx" instead of "14.xxx" on 20 meters and "29.xxx" instead of "28.xxx" on the lower 10 meter bands. Go figure.

I couldn't solve this, so I purchased and installed a new LCD counter/display and put the DG-1 on the shelf. Perhaps you will have better luck than me!

One other thing you can try if you have the ability to measure low-level RF signals is to calibrate the counter input signal (ccr) from the IF board. A low signal level will sometimes cause an unstable display, but this is a bit of a long shot. The instructions are in the Service Manual, which you can download on-line if you are comfortable with this type work.

Good luck!

Well I think important thing to realize is that we need to give the KW design engineers the benefit of the doubt when it comes to designing all the circuits and the associated component selection to meet the design performance goals.

Of course as parts become unattainable will come times when we have to select substitutes. Helps if we have some level of design basis understanding to make good selections. As hams some of us will also always be looking to improve upon the design and that is OK. Some of us are better at that then others. Sometimes those improvements get picked up by the manufacturers. Often times the "improvements" are subjective,self-fulfilling, and anecdotal and have no measured factual basis.

I think among the very first mods was the substitution of non-KW xtal filters. Also, have been those who changed out RF amp dual gate mosfets. Cant forget the hot rodders or QRO boys. Also, a few who felt compelled to install high volume and high noise cooling fans not realizing that the original 120vac fan running on 100 vac was done by design to produce a very quiet fan because the radios have very good RF compressors/clippers and no one wants to listen to hurricanes on anyones signal when running with the processor on.

Lastly, there are advances in technology and components available today that werent there for KW engineers. One example is Schottky diodes like the 1N5711 or CDSH270 that some of us have installed in the Balanced Modulator and Product Detectors. With the resulting better carrier suppression we get reports from owners of quieter receivers and less audio distortion than what the 1N60 germanium diodes produced.

As to the 900vdc anode supply it is not a regulated supply. Unlike the 9vdc supply that can supply a constant 9vdc under varying DC load resistance the anode supply has a design percentage regulation both key down static regulation and cw/ssb mode dynamic regulation. Cant just use the key down anode voltage and current to calculate Rp. Have to use the K factor which takes in to account the tubes conduction angle for a Class AB1 tube. Only way to use the DC values is in a Class A amp. Once you calculate Rp then need to know the transformer ESR inorder to understand where the IR drops are occurring which produces the supply voltage % sag.

You have to ask yourself why did KW provide the HV meter position? How do you use it to operate the transmitter? Trying to watch it during SSB or CW mode operation would be pretty meaningless. Do we really use it to determine the tube plate dissipation? Does anyone care? If we load to no more than 200 to 225ma we know we will be within the tubes dissipation ratings. Do we use it to troubleshoot ie see if we have anode voltage available? If so, not very valuable as it is not measuring the voltage at the 6146 anode caps. Could have output from the doubler supply and nothing on tube anodes. Or do we just use it to see if we have 900 vdc at the output of the doubler versus having 450vdc at the output? I guess the latter is probably the most valuable indication it provides. When we see half voltage pretty good bet we have lost one of the two filter capacitors. Maybe safety was even considered? If we give them a front panel 900vdc voltmeter maybe will keep them from going under the covers to measure it?

Well we have come pretty long way from original question about why folks are installing 150uf or 180uf caps in lieu of the original 100 uf caps and if they are doing it to realize improvement in the dynamic regulation. Unless someone has measured the before and after static and dynamic regulation and can produce the differences in % sag between 100uf caps and 150 to 180uf caps I think most are doing it as was previously noted so they can use the same 35 mm diameter package and the stock factory clamps and mounting holes. I have done zero measurements, but believe that any improvement in ripple and regulation would be minimal and an ancillary benefit.

Other thing you have to think of with any mod (a parts substitution is a mod) is did we return radio to design function and did we introduce any other unintentional problem.

One thing that we have proved thru experience is that the additional capacitance doesnt present us with any problem from additional initial power on surge or inrush current. At least I havent heard of anyone adding lite bulb soft start circuits yet! Of course related to surge current we now can talk about the filter caps equivalent series resistance (ESR)!

I haven't had a good look at the DG-1 diagram. The TS-830 counter unit uses some TTL-logic (using a diode matrix to set severals pins at the big counter IC) so show the display according to the setting of the band switch. Altering this diode "ROM" you can set the counter to any display the module can show. After all, the counter sees only a 500kHz to 1MHz signal from the PLL regardless of setting the band switch. There are 13 logical inputs (for AUX to 29.5MHz band) at the counter module. Setting one of these pins to a logical "1" switches several internal logic pins to show the correct value at the counter. I'm fairly sure that you can program the counter to any frequency display from at least 1500 kHz to 29.500kHz in 500kHz steps altering the settings in the logical table by adding and removing diodes in the matrix.

To make a long speech short: the switching of the display from "15.xxx" to "14.xxx" is done by altering this matrix. If one of the diodes setting the logic levels at this circuit is faulty or has bad solder connections, the display will alter the fixed digits it shows (apart from the variable part following the input from the PLL).

My understanding of RF (and tube) topics isn't very deep yet. However, I spent some time with audio amplifiers and all kinds of problems around them. One thing (and a standing topic in audio-circles) is the value of a "hard" or "soft" power supply for audio PA. These days, everyone in PA circles use class D amplifiers, but in the "old days" of audio amps there were constant discussions how the remaining ripple on the power supply lines affects audio performance in the usual AB push-pull configuration amps. The standard configuration for the power rails in an audio amp is a transformer, a diode rectifier and two large caps in the 4700 ... 20000 uF range, no regulation at all.

The truth is that normal PA design gives you a wide margin of suppression for power supply ripple. It just doesn't matter if the +/- 60V power supply rails of your 120W audio amp has 10mV or even 1V ripple on it... you have some 60-80dB suppression of these ripples to your output signal, so even 2V ripple on the rails leads to <1mV hum on the speaker line...

I suspect the suppression of plate voltage ripple to output signal in a tube amp is less than these large margins in modern transistor designs. OTOH, we aren't talking about the "golden ears" of some hifi fanatic, so I think it should make no difference at all if you stay within the design parameters of the original design... not worse and not better.

Martin DB2MJ

Martin,
Very interesting and thoughtful comments. Although the displays have differences, I'm sure the TTL schemes must be similar, including the "bias" inputs from band switching. I'll study the DG-1 diagram with this in mind to see if I can identify and isolate suspect diodes for replacement or another soldering pass. This particular issue didn't occur before the re-soldering exercise, so I may have damaged a diode or altered a connection for the worse.
Thanks
Dave

52485. TS-830S HV power supply metering circuit

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-06-21 18:06:38 UTC
From: jwimmer@...
Topic: 52485 Message: 52485

Hello all, especially Terry and Mike,

I have a problem that has stumped me for a few weeks now. I've taken my TS-8300S offline to troubleshoot the metering circuit for the high voltage. I replaced it with my TS-530S temporarily until I repair the 830. Here's what I have. I get nothing on the meter when I put the switch in HV. All other positions work fine, so, I take the bottom cover off, and put a voltmeter on the HV pin. At this point, I should measure about 380mv DC. Nada....ok, so I measure the 800VDC pin, essentially the cathode of D4 and junction of R5. I get about 942VDC. Ok, that's good, so the combination of R5, 6, 7 in series with R8 to ground should give me the voltage drop I am looking for.

At the HV pin to ground with no power applied, I measure 100.7 Kohms. Seems ok given that R8 is a 100kohm resistor. At the junction of R6 and R7 and the cathode of D4, I measure about 792 Kohms. Seems low. I'm hesitant to take the board out to try and measure the junction of R7 and R8, or to measure DC voltage there but can't really see why I'm not getting any voltage on the HV pin. Otherwise, everything is pretty good with about 100W out on 80M with 200ma plate current.

Suggestions are welcome and appreciated!!

I just checked a good TS-830 Rectifier Unit I have and you should see
the following values:

1. Approximately 2.4Meg between the 800 terminal and HV terminal
2. Approximately 100K between the HV terminal and GND.
3. Approximately 1.46Meg between R5 and the junction of R6 and R7.

I rechecked the values with another ohm meter

1. Approximately 1.48Meg at the junction of R5 and the cathode of D4 and
the junction of R6 and R7
2. Approximately 98K between R8 to ground
3. Approximately 2.1Meg between HV and 800 terminals

73

Jeff

The HV voltage divider to drive the meter in the HV meter position it is a little tricky to understand at first glance. It is also common for the divider resistors to go high or even open.

In RX mode you should measure approx 45 vdc at the HV Terminal. The divider ratio in Rx is 2 meg / 100k = 20/1 or 900vdc/20 = 45vdc. If you dont read approx 45 volts then likely have open divider.

Now place the meter switch to HV and flip to Send and you should read approx 0.360vdc or 360 mv at the HV terminal. The divider ratio has been changed by placing the 800 ohm meter movement in parallel with the 100k divider resistor. Ratio now is essentially 2meg/800 or 2500/1 or 900vdc/2500 = 0.36vdc or 360mv.

The meter FSD is approx 0.40vdc.

The divider string will not effect your anode voltage or RF output power. Failure mode of carbon comp resistors is to go high or open so typically wont affect the 900vdc supply to the Finals anodes.

Did you try cleaning the meter selector switch with Deoxit? Can apply it with an artist brush to top side and let it work its way down in as you exercise the switch.

Rarely will have bad solder connection on the divider.

Mike said....

I just checked a good TS-830 Rectifier Unit I have and you should see the following values:

1. Approximately 2.4Meg between the 800 terminal and HV terminal
2. Approximately 100K between the HV terminal and GND.
3. Approximately 1.46Meg between R5 and the junction of R6 and R7.

Ok, given that, I get the following as measured with my Fluke and the meter sw in the HV position.
1. Approximately 2.1M between the 800 terminal and HV terminal for a second, then falling to 980k after a minute 30 seconds or so...still falling to about 950k ohms. (Problem in this area)2. Approximately 100.8k between HV terminal and GND. (R8 is good)3.
 Approximately 1.6Meg between R5 and the junction of R6 and R7. (R5 and R6 are good)
Mike, I believe R7 is bad....but it doesn't look bad i.e., not burned, and since they're only 1/4w resistors, it doesn't make sense, but then, that's electronics. I guess I'll take the board loose and get the soldering station and solder wick out and see what's up....unless you have any other suggestions.
Jeff

Mike,

I have my Fluke 75 on the terminals now, HV and 800, and I'm seeing .931M up to .940M and slowly climbing. I don't know of any electroytics in that circuit that would be charging up from the fluke's battery......this really has me stumped.

I am not sure why you are measuring from 800 post to ground when you know you have good anode voltage and 100 watts RF output?

You are seeing the charge current on the HV filter caps and the effect of the bleeder resistors.

Momentarily short out both HV filter caps to drain charge and take measurements quickly.

You are looking at the 2 meg divider string, 2 meg diode equalizing, and 1 meg of bleeder all in parallel.

It is very difficult to make any sense out of resistance readings with the board in circuit with all the parallel paths and charge current and bleeder action on the filter caps.

If you have approx 925vdc on the 800 post and dont have approx 41vdc to 45vdc volts on the HV post in Rx mode then you have an open in the divider string. As I previously said not uncommon for R5,R6, R7,R8 resistors to go high or open or bad solder connection.

Again if no 40 vdc on HV post in Rx mode wasting time taking resistance readings. You will have to pull the board.

52493. Hybrid Net Update (June 21, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-06-22 03:14:59 UTC
From: Mark Gilger
Topic: 52493 Message: 52493

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by me, WB0IQK. There
were 33 stations checking in under good band conditions.

We had the following number of radios checking in.

6 running TS-520(x)
3 running TS-530(x)
3 running TS-820(x)
6 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
1 running TS-900

He was running a TS-900 with my L-4B AMP.

The Sunday net was run by me, WB0IQK. There were
16 stations checking in under poor good
conditions. We had the following number of radios checking in.

4 running TS-520(x)
2 running TS-530(x)
1 running TS-820(x)
0 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
1 running a TS900

The rest were running non Kenwood hybrid equipment.

He was running my TS-900 + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total = 142, Sunday☐s total = 88
December 2014, Saturday☐s net total = 92, Sunday☐s total = 86
January 2015, Saturday☐s net total = 110, Sunday☐s total = 84
February 2015, Saturday☐s net total = 103, Sunday☐s total = 98
March 2015, Saturday☐s net total =80, Sunday☐s total = 51
April 2015, Saturday☐s net total = 59, Sunday☐s total = 29
May 2015, Saturday☐s net total = 79, Sunday☐s total = 48
June 2015, Saturday☐s net total = 70, Sunday☐s total = 38 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Good Day

Its a complete station, in VG working order. full power on all bands. just add an antenna and your on the air.

SSB and CW filters installed.

VFO readout is now working well [I resoldered the connections as it was intermittent] Rock steady now.....

lamps are all working. I replaced 2.

Included:
ts-820s with power cord.
sp-820 with the cable
matching Ext VFO with the cable
MC-50 microphone in good working order.
NEW Micronta SWR & Power meter 20 - 2000 watts. [Radio Shack]

pictures are available on request.

shipping to conus is fine I pack and ship goods for a living.... all items will be bubble packed and boxed then shipped in an overpack. buyer pays actual shipping.

Demos are available on request, local pick up is fine.

K3RJB please use my QRZ contact info.

Asking 525 plus actual shipping. no discussions here please contact me off list for offers and info.

Did you try cleaning the meter selector switch with Deoxit? Can apply it with an artist brush to top side and let it work its way down in as you exercise the switch.
Rarely will have bad solder connection on the divider.

Terry, as you probably sent this before my last email to Mike, I believe R7 has failed. I knew I should be getting about 370mv or so on the HV pin in the Send mode, and that's what got me looking at the voltage divider for the meter circuit. I also knew it shouldn't have any affect on my anode voltage as the rig was still tuning and transmitting fine, thank goodness!!
Just the fact the meter HV circuit wasn't working irritated me to the point of putting my 530S back in service once I replaced the 2 HV caps, resistors, and ceramic caps. Lost half my high voltage on that radio so figured I'd replace those caps before catastrophe happened. Once replaced, that radio is now my main, and I can take the time to work on this irritant.
I had not worked out the math for the 45vdc, probably because I didn't know the meter resistance, but knew 0vdc wasn't right either way, I did know the meter should read about 370mv depending on the level of anode voltage so there we are.
I have put a bit of Deoxit D5 on the switch last week, and a tad more this morning and worked the switch back and fourth to clean the wiper, no joy. SO, as I told Mike, I'm just going to have to get the soldering station and solder wick out and take R7 lose first and check it's value. Something tells me it's going to be bad. I had misspoke and said 1/4w earlier but I think those are 1/8w carbon film resistors so it's off to digikey or Mouser to order a handful since I have 3 radios, might as well add a few extra to my spares kit.
Thank you sir
73Jeff - W5JGW

Hi Jeff,

You've confirmed you've got HT and your radio
puts out 100W and you know the meter works well
on other positions. So the problem is down to the
meter switch or the voltage divider on the HV
unit. Doing all these resistance measurements
might be interesting but it will be a lot faster
to pull the board and check R5, R6, R7 for
completeness check R8 & C1. If that doesn't give
you an answer check the solder traces connected
to those resistors and if that gives you nothing
trace the wiring and switch from the HV measuring point to the meter.

High value resistors have a tendency to creep up over time.

Good luck.

Jeff:

I thought you addressed this problem to both of us that is why I responded. You dont need a lot of cooks in the kitchen. So I will offer this one last tip.

In my experience trying to trouble shoot power supply and power supply loads with an ohm meter isnt very practical due to all the parallel paths and complication that filter caps present. Powering the circuit and reading IR drops is best method.

So with that before flipping the board over to inspect and replace divider resistors you can safely power it easily and test your divider string.

First you know you are looking a 3 x 680k for around 2.04 meg. You also know it most likely has gone somewhat higher over time. So your "typical normal" ratio will be from around 20/1 to perhaps 22 or 23/1.

So using a 12vdc bench supply, or a couple of 6 volt lantern batteries, or even a 9 vdc transistor battery apply the negative lead to chassis ground and the positive lead to the 800vdc wire wrap post. Now measure the millivolt voltage at HV wire wrap post. With 12vdc applied should see approx 0.54vdc or 540mv. With 9vdc applied should see approx 0.44vdc or 440mv.

This is a much better test than taking ohm readings.

I have measured the internal R of all the KW hybrid meters and the 500ua meter movement of the 530/830s is nominal 800 ohms and 0.40 vdc full scale deflection. Dont try to measure with an ohm meter.

I connected two 6vdc lantern batteries in series producing +12.32VDC
applied to the Rectifier Unit's "AC800" terminal and ground return to
the GND pin.

I measured the following DC voltages:

Cathode of D1 and anode of D2 = +6.1VDC
Cathode of D3 and anode of D4 = +11.95VDC
Junction of R5 and R6 = +7.49VDC
Junction of R6 and R7 = +3.98VDC
800 terminal = +.5VDC

My TS830 Rectifier Unit is completely disconnected from the power
transformer and any HV filter capacitor so there's no chance for
external components interfering with the voltage readings.

Thank you Mike and Terry both I've been hesitant to unwrap the wire wrapped input and output connections, mainly because re-wrapping them is no easy task without a good wirewrap tool. I supposed I can just solder them back on, but you both make excellent cases for needing to do this as opposed to as Terry said, chasing parallel resistors and the charging of caps which all contribute to phantom readings with an ohmmeter. I've ordered 10 680k resistors for bench stock, and because I feel at least one of them has to be failed. With 3 radios, I'm bound to need them at some point. I have taken the board loose from the radio, albeit with all connections still in place to check the trace side of the board for any bad solder joints. None are visible. These resistors aren't listed in the parts list, since they're not unique. They look to be 1/8w resistors. I don't think the leads from 1/4w resistors will fit through the board solder pad. Tonight I'll take the inputs and outputs loose and use a bench power supply to apply 12 volts as you both have suggested, and make measurements accordingly. I appreciate both of you and your suggestions. I hope I haven't sounded like I was clueless, as I've been doing component level maintenance since my days after tech school here at Keesler AFB, in 1973. Yes, it's been a while, so refreshers are always welcome. I'll let you know my results tonight. 73Jeff - W5JGW

My TS-830 Rectifier Unit came with a TS-830 power transformer I purchased from Bob Mansker KE5FTF last winter. There are no filter capacitors connected to the Rectifier Unit. I simply cut all connections between the Rectifier Unit and the power transformer resulting in the Rectifier Unit completely disconnected from all possible components that would interfere with the voltage and resistance measurements.

Today a 1/4 watt metal film resistor is much smaller physically.

Calculate the current with 940 vdc at the cathode of D4 and I think you will find it to be approx 440ua. Calculate the power that the 680k and 100k resistors must dissipate. Remember that the 100k sees approx 45vdc in Rx mode. You can use I squared R.

I think it will be around .130 watts for the 680k units so a 1/8 watt (.125) wouldnt be adequate. I would order 1/4 watt resistors. 1/8 watt would be OK for the 100k, but I would just install all 1/4 watt resistors.

Also, how important is HV voltmeter accuracy to you? If important then buy 1% tolerance resistors. If not then order the stock 5% resistors.

Check my math as did back of envelope calcs. Better to use on line calculators.

Hi Kenwood users or members;

I am on the search to obtain a service manual for my Trio Kenwood 5R-59DS communication receiver.

I do have the operating manual with enclosed the original schematic.

But most of the sensitivity is gone on the different bands !

I think some resistances are out of there tolerance.values

I presume to change them by new ones with original values.

After done so I like to do some allignement of the whole receiver.

A copy or a pdf file is also welcome of the original service manual.

All further information around this equipment will be welcome.

Best regards Jean ON4AEF.

Jean,

I have the Kenwood R-599S and T-599S service manuals on my website

www.w5rkl.com

Simple click on the "Manuals and Documents" link. When the page comes
up, click on #1 (R599S) and #2 (T599S) links to the service manuals.
Download the manuals one at a time.

Hi To All. Mike the receiver Jean is asking about is the 9R-59D which is an all tube receiver circa 1968-69 AD. The PA3ESY.nl web-site has the op manual but not the service. It may be that K-wood didn't release separate service manuals for this unit. Google may be his best friend here.

I have an old dummy that measures 45 ohms. Is that within acceptable limits to safely connect to a KW hybrid? Will it cause Tx tune up problems or possible damage? Am I better off junking it or rebuilding it with much closer value to 50 ohm? Thanks,
John

Hi Rob,

It's resistance is a little on the low side but as a quick guide you can do the math

50 / 45 = 1.1 SWR indicating you could use it with a transmitter designed to operate into 50 ohms. Certainly your hybrid will be ok with it from a resistance point of view. You didn't tell us the power handling capability of the load.

If it's a homebrew job with multiple resistors in it you might want to have some fun and pull it apart to understand why it ready low.

Regards

Lou

G' day all:

Well, I am new to this group and Kenwoods as well, and to make a long story short, a recent trip to Ontario resulted in me dragging home yet another vintage find, a set of very nice R-599D/T-599D twins, sadly without the S-599.

Things are going well as far as getting them up and running but I have run into an issue with neutralizing the finals on the T-599D.

First of all, I have researched the previous posts and have found some interesting new info (to me!) that should help going forward. That said:

1) The original finals test as new, or better, on a TV-7, even better than most of my spare 6146's.
2) Cathode and screen resistors are all within spec.
3) There is no obvious evidence of oscillation at any frequency.
4) Power output appears good - 120w on 80 and 40M, 110 watts or better on 20M, and about 90 watts on 10M.
5) I have used a scope to minimize the output with the screen voltage off and it does so very nicely near mid-range, or so, on the neutralizing cap.
6) Per one of the postings on this group, I re-peaked the Tune and Load (on 10M) after each of several efforts to minimize the RF throughput. (Thanks for that suggestion - it did improve things!)

That resulted in max RF out coinciding very well with the Plate dip on 80/40/20M, but not on 15 and 10M. I guess the bottom line is, should I worry about it? Tuning is smooth, no jumpiness, output seems about right. I am leaning towards buttoning it up.

Any opinions or suggestions?

Thanks in advance.

Peter,

The T599 neutralizing procedure is found on page 10 paragraph 9 "NEUTRALIZING adjustment" in the T599 service manual. If you do not have the T599 service manual, you can download it at the following link:

http://w5rkl.com/wp-content/uploads/2014/04/T599S-Service-Manual.pdf

Kenwood recommends performing the T599 final amplifier neutralizing procedure on 15 meters at 21.225Mhz. If you follow the procedure outlined on page 10 paragraph 9 and have the same results then button up the transmitter and have fun.

Brian,

Most exciters and linear amplifiers have a 50 to 75 ohm impedance range, a bit more on the low and high side. You can find the exciter or amplifier's output impedance range by reading the exciter or amplifier operator/user manual's "Specification" page.

I misspoke on amplifiers. For example, the Ameritron AL-811/811H specification page states for full output the impedance should be 50 ohms at less than 3:1 SWR.

Exciters such as the Kenwood hybrids, Heathkit SB/HW series transmitters/transceivers, and others have an impedance range between 50 and 70 ohms so a 75 ohm dummy load should be okay.

In short, refer to the amplifier/exciter operator's manual for further details.

52519. TRIO KENWOOD 9R-59DS (communication receiver)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-06-27 14:46:58 UTC
From: Behiels jean-Pierre
Topic: 52519 Message: 52519

Hi members;

I am on the way to restore a old communication receiver 9R-59DS.

I do have repeared the power supply,I do have receiving signals now.

But I do have very poor sensitivity on the ham bands in CW-SSB mode.

I saw on the schematic there is a remote connector on the back of the RX

I aw that on this connector pins 1 and 3 are tiered together !!!

That means when the S1C switch on the front panel(mode switch) is in the SSB-CW mode that a part of the RX antenna signal is connected to earth ???

Is this a normal standard wiring on this plug ?

I am thinking this is wrong ?

Concerning the user manual this socket on the back is used for operation in conjunction with a transmitter ?

They call it REMOTE PLUG !!!!

Are there any other members who have some experience with the use of this communication receiver ?
My opinion till now the sensitivity in AM mode is quit normal,also the audio output is quit strong by a few turns on the AF gain potmeter.

But is the SSB-CW mode the sensitivity is poor and the audio output is also very poor even with the AF gain full clockwise (100%)

Maby in this mode due bad wiring on the REMOTE plug ?

I hope someone could me set on the right way for further repear of this hamtoy hi..

Kindly regards Jean ON4AEF

The amp manufacturers will list an output matching capability in the spec page of the operating instruction manual.

Usually it can be a little cryptic. For example saying something like "50 ohms not to exceed 3:1 SWR". What does that mean?

What they really mean is that the adjustable Pi- or Pi-L network will match the impedance that a 50 ohm transmission line (coax today) presents to the SO-239 connector not to exceed 3:1 SWR and that then means a range of from approx 16.66 ohms to 150 ohms (50/3 and 50x3). They seldom talk about any reactive capability.

Your 75 ohm dummy load falls in there nicely.

The limiting factor is almost always the plate spacing of the Plate Load capacitor that the designers speced and installed.

You can calculate the RF voltage by multiplying the output power by the load impedance and taking the square root. For example at 1000 watts and a 150 ohm load (3:1 SWR) the voltage would be the square root of 1000 x 150 = 387rms rf volts. Peak RF volts across the Load cap would be approx 1.414 x 387 = 547 volts. Greater than what most broadcast band spaced plate load caps could handle. Good design amp would have a real Plate Load cap. You can measure the plate spacing air gap carefully with set of feeler gauges and when you have that can go to engineering tables to see what the break down voltage for that air gap is.

Of course need to have some headroom for tuning errors and for faults on the feedline. An open being the worse case as Z goes very high so SWR goes very high and RF voltage goes very high.

Another good use for DC Hi-pot is testing Plate Load caps and Plate Tuning caps for that matter.

Don't know the receiver but the plug is probably used to mute the
receiver when you are transmitting and requires a shorting plug
when not connected to a transmitter.

Topic: 52526 Message: 52526

Hi folks,

after a few weeks of flawless work (and many QSOs) my TS-830S suddenly developed a malady. When touching the VBT knob, the sound gets very thin and tinny. Bass is completely missing. VBT is fully CW. Most of the time, I'm able to restore the full sound when pulling and/or pushing the knob and/or turning it a little to the left and than turning it back completely CW.

This seems to be a contact problem at one of the wipers of the two VBT pots. According to the diagram, there are two pots on the same axle for VBT. Is this a known problem and what can I do? Is possible to disassemble the whole unit (there is another pot in it for tone) and clean/adjust it. The tone pot has contact problems, too (scratchy and intermittend when turning it).

Thanks for suggestions,

Martin DB2MJ

52527. Magicom Instruction Sheet

Martin,

Have you tried applying a cleaner like DeOxit-5 to the pots and working them repeatedly? A short spray into the pot (using the applicator tube that comes with the can) and running through the full range of motion many times to allow the cleaner to work will often cure this type of problem. I'd try this before any disassembly or replacement efforts, as the success rate is pretty high.

Dave

Martin, If you have any Deoxit D5, spraying a very small amount into both pots where the 3 leads come out of the round metal case and moving the pot back and fourth should clean the interior wipers of both pots, since they tend to build up corrosion over time. That should fix you right up. 73Jeff - W5JGW

Fellows your hearts are in the right place, but me thinks that you have never seen the VBT or IF shift pots in a TS830 rig?

This pair of concentric shaft PC board mounted pots have no clear access to the three leads like a single panel mounted pot typically would have.

You have to roll the AF board over just to have any hope of spraying contact cleaner at them let alone getting any cleaner in them. The 830 of all the rigs is the most difficult to get any meaningful amount of contact cleaner in to most of the sub panel mounted pots.

Some people claim that they have success by setting the radio in styrofoam shipping brace and removing the front panel and then injecting contact cleaner at the pot shafts and letting it migrate in to the pots past the shaft bushing lube. I have never found that a very viable method.

Terry K9TW

52531. Re: TS830S: Thin and tinny sound when wiggeling at the VBT pot

I forgot to mention that if you roll the audio board over you maybe able to fashion a very small diameter tube with a very short right angle bend on the end that can help direct some spray toward holes in the pot housings. Also, the VBT and IF Shift pots on the 830s often times simply have excessive wear. If you grasp the knob and raise up and down and/or side to side and you notice changes then cleaning isnt going to fix excessive radial play.

I forgot to mention that if you roll the audio board over you maybe able to fashion a very small diameter tube with a very short right angle bend on the end that can help direct some spray toward holes in the pot housings. Also, the VBT and IF Shift pots on the 830s often times simply have excessive wear. If you grasp the knob and raise up and down and/or side to side and you notice changes then cleaning isnt going to fix excessive radial play.

Dave:

Knowing you and your abilities it wont surprise me that you can come up with a method and hopefully share it with me. Yes a lot more clearance and access in the 820 series.

I have a couple spare VBT/IF Shift PC boards here and have played around with different ways to access the 4 pots and havent come up with a method that doesnt require rolling over the Audio Board and really works very well.

Topic: 52535 Message: 52535

All:

I know this is unlikely but I am looking for the bandswitch knob for any of the R599/T599 series. Mine is missing the metal-like square insert out of the side opposite to the pointer. I know I could make a reasonable facsimile but thought I'd go fishing here first to see what might be out there. I believe any of that series should work, although the ideal one would be one from an R599D with the black knobs.

Thanks and 73

Peter

Hi Everyone. I have a t-599 transmitter that has a problem. I hope someone can help. It tunes up just fine on 80 meters. Full output. On 40 and 20 sometimes I can get it to tune but not using the regular procedure. I have to go to RF on the meter selection and it is touchy but at times I can tune it up. Other times I can only get 2 or 3 watts out. Same on 15 and 10. Can only get 2 to 3 watts out. Thanks in advance for any help someone can give me. Bill WR4G

I ran into this mod a few years ago but could never find an actual data sheet. I did find several references from a search that said when removing the Magicom board to replace C133 and C139 as well as R105 and R110.

There was also a reference to an article in the November 1978 “73 magazine”, but I have not seen it.

There was also some mention of a substitution of the two MOSFETS in the front end with parts that had the markings removed. This was marketed about the same time.

CQ Magazine ran an article on it. "The Magicom RF Processor Module in a TS-820S", October 1978, page 52. Couldn't find anything in 73 Magazine.

52540. [TS-520_820_530_830] 9R-59DS Communication receiver

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-06-30 03:04:21 UTC
From: Behiels jean-Pierre
Topic: 52540 Message: 52540

Hi members;

I am on the way to restore a old communication receiver 9R-59DS.

I do have repeared the power supply,I do have receiving signals now.

But I do have very poor sensitivity on the ham bands in CW-SSB mode.

I saw on the schematic there is a remote connector on the back of the RX

I aw that on this connector pins 1 and 3 are tiered together !!!

That means when the S1C switch on the front panel(mode switch) is in the SSB-CW mode that a part of the RX antenna signal is connected to earth ???

Is this a normal standard wiring on this plug ?

I am thinking this is wrong ?

Concerning the user manual this socket on the back is used for operation in conjunction with a transmitter ?

They call it REMOTE PLUG !!!!

Are there any other members who have some experience with the use of this communication receiver ?
My opinion till now the sensitivity in AM mode is quit normal,also the audio output is quit strong by a few turns on the AF gain potmeter.

But is the SSB-CW mode the sensitivity is poor and the audio output is also very poor even with the AF gain full clockwise (100%)

Maby in this mode due bad wiring on the REMOTE plug ?

I hope someone could me set on the right way for further repear of this hamtoy hi..

Kindly regards Jean ON4AEF

Regarding the advice about using Deoxit-5, I think that might be unwise if they are carbon film pots. Caig Deoxit is meant for use on metal switch contacts. I think what you want for the pots is Caig Fader.

Hi Jean,

You said:

"/*I aw that on this connector pins 1 and 3 are tiered together
!!!*//*That means when the S1C switch on the front panel(mode switch) is
in the SSB-CW mode that a part of the RX antenna signal is connected to
earth ??? *//**//*"*/

No, that's not true.

Follow the wiring from pin 3 of US socket. It goes to 4 places

1. To one lead of RF amplifier grid resistor R2 (1Meg) "Point B"
2. To one lead of IF amplifier grid resistor R9 (100K)
3. To resistor R16 (820K)
4. To terminal "5" on the FUNCTION switch S1C "SSB/CW"

Placing the FUNCTION switch to SSB/CW simply grounds those resistors but
does not ground the antenna.

The US socket "jumper plug" is correct.

73

Thanks fellas.

I have seen the mentioned CQ article. Have seen the mosfet front end mod installed in a couple of TS520 rigs. This 820 does not have the RF board mod just the processor mod on the IF board. R105/R110 are both original 10k units.

Yes the limiter IC package installed on this board has no markings either. I dont care as not interested in reverse engineering. Just want IF board returned to factory design config.

What is silly is if you align the factory processor (rf compressor) correctly (disregarding the service manual instructions) it works very well. In fact if you dont use too much comp level the tonal quality sounds very good. To my ear better than the TS830 which is a clipper.

I had to order replacements for C133 and C139 as didnt have correct physical size. Have unsoldered all four leads from the mod board to foil side of IF board and ready to reinstall the two caps. Will then proceed with alignment and will soon find out if anything else was changed. My guess is will be back to stock config and performance.

Appreciate your feedback.

Terry,

Interesting differences in the speech processors: 820S with an RF compressor, 830S with an RF clipper, and now I am reading that the 530S has an audio speech processor, apparently not RF based at all. Any idea why the differences in approach?

Also, have you posted anything on aligning the 820S processor or do you mind passing your procedure along?

Thanks!

Dave

Afternoon Mike;

Yes thats true Mike,but pin 1 of US connector is connected to ground (standardly ??) !!!!!!!!!!!!!!!!

There is a wire jumper between pin 1 en 3 of US socket ??

That means that pins 3 of this connector is also directed to ground !!!!!!!

That means that all the derived connections you talking about are wired to ground isn’it ??

Resuming :

Connection B = antenne input signal is connected the common of S1C and in position 5 of S1C connected to pin3 of US socket.

And comes in this S1C switch position again to the ground by means of the pin1 jumper wire to pin 3 of US socket ?

Because pin 1 and 3 on US socket are bridged by a wire hier Mike …

There should be possible some receiving sign from antenne but weaked by a ground wire not ??

I can not follow this kind of matter and wiring ?

Regards Jean ON4AEF

Hi Mike;

About your RED COMMENT :

In that way you have it correct Mike !

But what happen with grounding grid resistor R2 of the RF amplifier.

Does it not attenuate the RX sensitivity ????

I must say I am not realy a tube expert …

I stay with my opinion the RX sensitivity in CW-SSB mode of switch S1A/E (function switch on frontpanel) on the hambands is very poor !!!!!!!!!!

I do have to turn the audio AF gain fully clockwise on this position of switch S1A/E to hear some few stations..

In the AM-AM/ANL position of switch S1A/E,I do have a lot of AF gain into the speaker hi hi..

So what happens I do not understood very well …

Regards Jean ON4AEF

Subject: Re: [TS-520_820_530_830] 9R-59DS Communication receiver

Hi Jean,

You said:

"I aw that on this connector pins 1 and 3 are tiered together !!!That means when the S1C switch on the front panel(mode switch) is in the SSB-CW mode that a part of the RX antenna signal is connected to earth ??? "

No, that's not true.

Follow the wiring from pin 3 of US socket. It goes to 4 places

1. To one lead of RF amplifier grid resistor R2 (1Meg) "Point B"
2. To one lead of IF amplifier grid resistor R9 (100K)
3. To resistor R16 (820K)
4. To terminal "5" on the FUNCTION switch S1C "SSB/CW"

Placing the FUNCTION switch to SSB/CW simply grounds those resistors but does not ground the antenna.

The US socket "jumper plug" is correct.

Hi members;

I am on the way to restore a old communication receiver 9R-59DS.

I do have repeared the power supply,I do have receiving signals now.

But I do have very poor sensitivity on the ham bands in CW-SSB mode.

I saw on the schematic there is a remote connector on the back of the RX

I aw that on this connector pins 1 and 3 are tiered together !!!

That means when the S1C switch on the front panel(mode switch) is in the SSB-CW mode that a part of the RX antenna signal is connected to earth ???

Is this a normal standard wiring on this plug ?

I am thinking this is wrong ?

Concerning the user manual this socket on the back is used for operation in conjunction with a transmitter ?

They call it REMOTE PLUG !!!!

Are there any other members who have some experience with the use of this communication receiver ?
My opinion till now the sensitivity in AM mode is quit normal,also the audio output is quit strong by a few turns on the AF gain potmeter.

But is the SSB-CW mode the sensitivity is poor and the audio output is also very poor even with the AF gain full clockwise (100%)

Maby in this mode due bad wiring on the REMOTE plug ?

I hope someone could me set on the right way for further repear of this hamtoy hi..

Kindly regards Jean ON4AEF

Jean,

Your problem is not caused by grounding the lead of V1 grid resistor R2 (1Meg) as you continue to believe. Your problem appears to be caused by a possible failure in the BFO OSCILLATOR V7A.

SSB/CW uses V6 PRODUCT DETECTOR and BFO OSCILLATOR V7A.

AM works because AM detection does not use Product Detector V6 but rather diode detector D4. The Product Detector is disabled in AM mode.

A Product Detector is a "Mixer". The receiver's IF signal (V5) AND the BFO signal (V7A) are applied to the Product Detector V6. The 2 signals mix and produce a "Difference" output signal. The Difference signal is the "Recovered Audio". The "Recovered Audio" is fed through RF filter consisting of C25 (680pf), R30 (10K), and C30 (680pf). The filter blocks/grounds any residual RF allowing only the Recovered Audio to pass on to the audio amplifier, V7B and V8.

IF the BFO oscillator is not working then you will experience the symptoms you have. Check the cathode voltage of V7A, pin 3. If you find +10VDC then V7A is not oscillating, possibly due to a failed connection between V7A pin 3 and FUNCTION switch S1A terminal 5, broken wire or bad contact on S1A.

Jean,

I meant to say the BFO stage, V7A, is disabled in AM mode by lifting the cathode of V7A above ground. Product Detector V6 is not disable in AM mode but the Product Detector V6 is not used in AM. You can easily see this by following the AM signal using the block diagram and looking at the FUNCTION switch settings in AM and SSB/CW.

The AM signal flows from the last IF amp, V5, to diode detector D4. The recovered audio in AM flows through FUNCTION switch S1B terminals 2 (AM) or terminal 3 (AM Noise Limiter turned ON) then on to inter-stage coupling capacitor C32 (.001ufd) to the volume control VR3. The audio at VR3's wiper is applied to the grid of preamp V7B and the output of V7B is applied to audio amp V8.

Dave

I have no idea why different approaches were used with each model. Each method has plus and minus attributes. Primarily has to do with the levels of harmonic distortion and cross mod distortion.

I havent written up the alignment procedure just made notes in my service manual copy. Ken K4EAA has some alignment info on his site I think under FAQs?.

Biggest error in the service manual is they have you adjust the 455 khz Carrier Insertion Oscillator for the Balanced Modulator to 451.4khz. Very odd? If you do that you wont have the audio in the passband of the 455khz ceramic filters that follow. These filters have bandwidth of approx +/- 1400 hz. Processor will sound very thin if you set the 455 khz carrier oscillator to 451.4khz.

I usually inject 1200hz into the mic line and adjust the carrier oscillator trimmer cap TC-4 for maximum signal level at TP2. With .3mv input will see something on order of 650mv P-P at TP-2. This usually results in the carrier oscillator being adjusted to around 452.5khz to 453.5khz. At 350hz (6dB bandwidth) will see approx 325mv P-P level.

Morning Mike;

Outstanding Mike,I doi can follow now,great

Thanks for your good explanation around,things become more clearly now.

Like you say,I do measure on pin 3 of the V7A cathode a voltage of +1VDC.

But concerning the schematic I saw that this voltage is announced and should be +10VDC ????

But ones I am with switch S1A in the CW-SSB position this pin 3 of tube V7A is connected to ground by means of S1A.

So I could never have +10VDC on pin3 of V7A in CW-SSB mode ??????????

But I presume,I possible have this voltage when I am in AM mode,in this case pin3 connection of V7A is a open wire ..

But I do will check this again,what about and what exactly happens Mike.

Regards Jean ON4AEF.

Jean,

I meant to say the BFO stage, V7A, is disabled in AM mode by lifting the cathode of V7A above ground. Product Detector V6 is not disable in AM mode but the Product Detector V6 is not used in AM. You can easily see this by following the AM signal using the block diagram and looking at the FUNCTION switch settings in AM and SSB/CW.
The AM signal flows from the last IF amp, V5, to diode detector D4. The recovered audio in AM flows through FUNCTION switch S1B terminals 2 (AM) or terminal 3 (AM Noise Limiter turned ON) then on to inter-stage coupling capacitor C32 (.001ufd) to the volume control VR3. The audio at VR3's wiper is applied to the grid of preamp V7B and the output of V7B is applied to audio amp V8.
Your problem is not caused by grounding the lead of V1 grid resistor R2 (1Meg) as you continue to believe. Your problem appears to be caused by a possible failure in the BFO OSCILLATOR V7A.
SSB/CW uses V6 PRODUCT DETECTOR and BFO OSCILLATOR V7A.
AM works because AM detection does not use Product Detector V6 but rather diode detector D4. The Product Detector is disabled in AM mode.
A Product Detector is a "Mixer". The receiver's IF signal (V5) AND the BFO signal (V7A) are applied to the Product Detector V6. The 2 signals mix and produce a "Difference" output signal. The Difference signal is the "Recovered Audio". The "Recovered Audio" is fed through RF filter consisting of C25 (680pf), R30 (10K), and C30 (680pf). The filter blocks/grounds any residual RF allowing only the Recovered Audio to pass on to the audio amplifier, V7B and V8.
IF the BFO oscillator is not working then you will experience the symptoms you have. Check the cathode voltage of V7A, pin 3. If you find +10VDC then V7A is not oscillating, possibly due to a failed connection between V7A pin 3 and FUNCTION switch S1A terminal 5, broken

wire or bad contact on S1A.

Topic: 52540 Message: 52556

Hi Mike;

I do have measured again : about your RED comments.

I do have in AM mode 5.6VDC on pin3 of V7A and ZERO volt in CW-SSB mode.

On pin1 of V7A I do have 145VDC coming from OA2 stabilizer voltage.

On pin6 of V7a I do have 43VDC

On pin5 of V7a I do have 199VDC

I think no failure around this subject ?

Regards Jean ON4AEF

Jean,

I meant to say the BFO stage, V7A, is disabled in AM mode by lifting the cathode of V7A above ground. Product Detector V6 is not disable in AM mode but the Product Detector V6 is not used in AM. You can easily see this by following the AM signal using the block diagram and looking at the FUNCTION switch settings in AM and SSB/CW.

The AM signal flows from the last IF amp, V5, to diode detector D4. The recovered audio in AM flows through FUNCTION switch S1B terminals 2 (AM) or terminal 3 (AM Noise Limiter turned ON) then on to inter-stage coupling capacitor C32 (.001ufd) to the volume control VR3. The audio at VR3's wiper is applied to the grid of preamp V7B and the output of V7B is applied to audio amp V8.

Your problem is not caused by grounding the lead of V1 grid resistor R2 (1Meg) as you continue to believe. Your problem appears to be caused by a possible failure in the BFO OSCILLATOR V7A.

SSB/CW uses V6 PRODUCT DETECTOR and BFO OSCILLATOR V7A.

AM works because AM detection does not use Product Detector V6 but rather diode detector D4. The Product Detector is disabled in AM mode.

A Product Detector is a "Mixer". The receiver's IF signal (V5) AND the BFO signal (V7A) are applied to the Product Detector V6. The 2 signals mix and produce a "Difference" output signal. The Difference signal is the "Recovered Audio". The "Recovered Audio" is fed through RF filter consisting of C25 (680pf), R30 (10K), and C30 (680pf). The filter blocks/grounds any residual RF allowing only the Recovered Audio to pass on to the audio amplifier, V7B and V8.

IF the BFO oscillator is not working then you will experience the symptoms you have. Check the cathode voltage of V7A, pin 3. If you find +10VDC then V7A is not oscillating, possibly due to a failed connection between V7A pin 3 and FUNCTION switch S1A terminal 5, broken wire or bad contact on S1A.

Hello Mike,

Concerning the working of the BFO oscillator.

I do can receive and tune into CW/SSB signals,so I presume the BFO is working well ?

But like I say before signals (or audio output) into CW/SSB mode are weak,poor sensitivity seems to me..

Dave

I have no idea why different approaches were used with each model. Each method has plus and minus attributes. Primarily has to do with the levels of harmonic distortion and cross mod distortion.

I havent written up the alignment procedure just made notes in my service manual copy. Ken K4EAA has some alignment info on his site I think under FAQs?.

Biggest error in the service manual is they have you adjust the 455 khz Carrier Insertion Oscillator for the Balanced Modulator to 451.4khz. Very odd? If you do that you wont have the audio in the passband of the 455khz ceramic filters that follow. These filters have bandwidth of approx +/- 1400 hz. Processor will sound very thin if you set the 455 khz carrier oscillator to 451.4khz.

I usually inject 1200hz into the mic line and adjust the carrier oscillator trimmer cap TC-4 for maximum signal level at TP2. With .3mv input will see something on order of 650mv P-P at TP-2. This usually results in the carrier oscillator being adjusted to around 452.5khz to 453.5khz. At 350hz (6dB bandwidth) will see approx 325mv P-P level.

Dave:

If after reading Kens write up you need help contact me off the list to discuss. Other issue is the 0.30mv audio input signal level into the mic jack. Not too many owners would have an accurate and stable 1000hz source at that low a level or a means to measure it. Could use a step attenuator and a true RMS ac volt meter, but not necessary.

Topic: 52527 Message: 52565

Well it didnt take long before someone asked about the 455khz ceramic filters in the TS820S RF Speech Processor circuit and if I knew what they were and if I had any specs on them and is it possible that they can go bad and be the reason for not being able to get the processor to work.

First lets refresh on what the basic circuit is. It uses typical voice spectrum audio (300hz to 3000hz) to modulate a 455khz carrier. It does that using a Balanced Modulator. The output is an AM modulated signal with two sidebands and a suppressed carrier. The USB range is the carrier plus the audio and the LSB range is the carrier minus the audio. It is called Double Side Band Suppressed Carrier or DSB-SC. The resulting signal is approx 6khz wide. With 3 khz of audio the range will be approx from 452khz to 458khz.

All three filters CF-1, CF-2, and CF-3 are Murata Ceramic Filters. They are model CFU455H units with a -6dB bandwidth of approx 7.5khz.

I have swept these filters both in and out of circuit. You can see an out of circuit sweep posted under the Photos page on my website. If you click on the image it should enlarge. I did this with 2k ohm terminations based on spec sheet information. I normally do not as a matter of routine sweep these filters. I have never had a TS820 on the bench that I could not align the speech processor so I have never seen a bad filter. It is normal for the filter Fc to be slightly skewed from filter to filter.

When you look at the filter sweep you will understand why the directions to set the Carrier Insertion Oscillator to 451.4khz wont get it.

OK I think we have beat this topic to death. If anyone is still having trouble aligning their processor contact me off list for individual help. It is highly unlikely due to a bad ceramic filter.

So about 3 years ago I bought a 520S off of eBay and the seller claimed it "worked". I did get it for a decent price so I was happy with it knowing that I would also soon have my license and be on the air. When I received it, I turned it on and the only thing that seemed to work was the fan. Checked the fuse and it was ok. I took the top off and it looked fairly clean and untouched. I'm not a tech but do like to figure out what's wrong with things. I did get my license a year later and by that time a gave me a great deal on a IC-730 so the 520 just sat there.

Here we are 2 years later and I'm finally getting a chance to look at it again. 1st problem I discovered was a black wire was broken off of the power connector. Soldered it on and yay! VFO light came on but no noise. The speaker connector looked like maybe it broke off at some point and somebody "fixed" it. I put some earphones on and plugged in and noise appeared. Dialed through the bands and where I knew there should be some signals there was nothing. By this point top and bottom covers are off and I'm looking all over for the obvious. Nothing seemed out of place, missing or burnt. Although it did have the smell of the magic smoke remnants.
As I was rolling it over, snap crackle but thankfully no pop. I shut it off and got a nice bright light out and started looking at it a little closer. I discovered what I think my main problem is or maybe it's the result of something more. What I found was, one the wires going to the remote VFO connector (pin # 6) was burnt and broken. Adjoining wires are also melted and still need to pull them apart to see if they are bare or ok. I know there is not a lot of room going from the top of the cabinet to the bottom. Could that wire have rubbed and shorted out? I know it's a shot in the dark to ask but may as well. What would another reason be that would cause it to burn like that? It is still worthwhile to pursue the reason why correct?

Sorry for the long story to get to the question but I figured it would be good to have a little background.

Dave:

Well, it sure makes you wonder what happened there, but all you can do is fix what you see and proceed from there. That kind of damage would alone be capable of shutting down the rig.

I recall a TS-820S I bought on ebay. I did not expect it to work right off but was unprepared for what all was wrong with it. Once I even rolled it over and a piece of wire, tinned on the ends and about 1 inch long fell out. I never figured out what that came from. But I finally fixed all the radio's problems. It actually took very few component replacements but a whole lot of troubleshooting and adjusting.

Good Luck!

Topic: 52568 Message: 52570

Dave,

You should have the TS-520S operator manual to learn how to operate the TS-520S and the service manuals to service your TS-520S transceiver. I have both manuals plus a high resolution TS-520S schematic on my website:

http://w5rkl.com/wp-content/uploads/2014/04/TS-520S-Operators-Manual.pdf

http://w5rkl.com/wp-content/uploads/2014/04/TS520S_service-manual.pdf

http://w5rkl.com/wp-content/uploads/2014/04/TS-520S_LARGE-Schematic_Hi-Res.pdf

Study the block diagram in the operator's manual, page 25, and the high resolution schematic. Also study the operator's manual "Circuit Description" section, page 26, to learn how the transceiver's stages work. You will need some basic test equipment to troubleshoot, take voltage checks, and adjust/align the transceiver. You should have a 50 ohm dummy load with a power rating of at least 300 watts (MFJ-260C) when testing and tuning the transmitter.

There are voltages in the TS-520S that can kill you. Following proper safety precautions when working around high voltage is a must!!!!

52571. HYBRID NET UPDATE (July 5, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-07-05 19:08:11 UTC
From: Mark Gilger
Topic: 52571 Message: 52571

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by me, WB0IQK. There
were 14 stations checking in under good band conditions.

We had the following number of radios checking in.

5 running TS-520(x)
1 running TS-530(x)
1 running TS-820(x)
7 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

He was running a TS-830s with my L-4B AMP.

The Sunday net was run by me, WB0IQK. There were
11 stations checking in under poor good
conditions. We had the following number of radios checking in.

2 running TS-520(x)
1 running TS-530(x)
2 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running a TS900

The rest were running non Kenwood hybrid equipment.

He was running my TS-940s + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total = 142, Sunday☐s total = 88
December 2014, Saturday☐s net total = 92, Sunday☐s total = 86
January 2015, Saturday☐s net total = 110, Sunday☐s total = 84
February 2015, Saturday☐s net total = 103, Sunday☐s total = 98
March 2015, Saturday☐s net total =80, Sunday☐s total = 51
April 2015, Saturday☐s net total = 59, Sunday☐s total = 29
May 2015, Saturday☐s net total = 79, Sunday☐s total = 48
June 2015, Saturday☐s net total = 70, Sunday☐s total = 38
July 2015, Saturday☐s net total = 14, Sundays☐ total = 11(Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Look at the schematic and see what is connected to Pin 6 and then measure the potential at Pin 6 with Function Switch in the RMT position. See if you obtain what the schematic tells you should be there (with nothing plugged in to the external VFO socket). Hint: 9vdc regulated.

Most of the time when a wire that has a supply voltage on it has melted insulation the problem has to do with what was plugged in to that socket and not a fault in the internal supply voltage or the socket.
Always good to try to understand the root cause of a failure when you can so you can prevent recurrence. However, not always possible to determine and sometimes with component failures the part just gets tired and dies.

Melted insulation on wires of course is always result of an overcurrent event. Trick then is to figure out the reason for the fault current.

Initial thoughts include a mis-wired Remote VFO jumper cable?

Terry K9TW

52573. Wiring color code

Topic: 52573 Message: 52574

Dave:

Depending on model year two different wiring schemes. Some use S4-5 contact on bandswitch in PA cage as interlock so no SG voltage on the Finals so cant transmit on 15 mhz WWV and other serial number 820s do not use these contacts.

Color codes consistent but two different paths.

Red = SG wire wrap post on Final board from the SG switch
Brown = SG voltage to the SG switch from the Mode switch S6-8 wiper.
White/Brwn = SG voltage from the CW/SSB contacts of Mode switch S6-8 to PD-1 on Final board.

If you have rig that uses S4-5 then Wht/Brwn wire from PD-2 on Final board goes thru hole in PA cage floor to S4-5. Then Wht/Brwn wire from S4-5 leaves PA cage and goes to Transverter switch.

If S4-5 interlock not used then Wht/Brwn wire from PD-2 goes directly back to Transverter switch.

Wht/Brwn wire on Transverter switch becomes Brown wire. Brown wire from Transverter switch goes to 22uf dual can filter cap and Brown wire from 22uf dual can back to 210A wire wrap post on HV rectifier board.

There is also a Wht/Brwn wire that goes to the HV Unit board to supply SG voltage to the Tune mode divider resistors.

If you are saying you have no SG voltage on Pin 3 of Final tubes then measure at SG wire wrap post and then red wire at SG switch, then Brown wire at SG switch, then Wht/Brwn PD-1/PD-2, then to Transverter switch and so on.

I have seen a broken brown wire at the SG switch and more rarely a broken wire at Mode switch and more than once had bad contacts on the S4-5 switch deck and impossible to clean the contacts so easier to eliminate the interlock. Since there are no TX Mixer or Driver stage LC components and no tap on the main Tank coil for 15mhz no need to run SG voltage thru the S4 bandswitch contacts. Lastly, have seen SG switch that had been hit and the metal tabs on the switch body were spread open and the switch handle would toggle but wasnt making any internal contacts inside the switch.

Terry K9TW

Terry;

Thanks for the reply. That information will help.

SG does not appear at the SG switch. The negative voltage is there and the switch is operational.

It is also missing at the 56k resistors (which have, based on experience, been changes) on the HV PWB.

There was SG when I replaced the original S3001 tubes with a pair of Taylor (not my choice - friends never listen <g>) 6146B's. Went to tune mode, advanced the "Carrier" controls slowly while monitoring IP. Something went "snap" and SG went away!

The voltage are good at the rectifier PWB. No damage there.

Disappears after that - really <g>!

I was hoping there was a reasonable wiring color code that would save me some time and head scratching.

I'll check out the Mode and band switches.

OK do I understand that you have it on both sides of R6 470 pi-filter resistor on Rect Board? If you place temporary jumper from 210A on Rect board to Brwn wire side of SG switch do you have SG voltage on the tubes? This is better test than ohming the SG switch contacts.

I assume you have checked at RF-3 pin 1 on RF board to see if you have it available for the Driver Tube? If you do that pretty much proves the supply is good.

Do you have it on the two brown lead wires on the dual can 22uf filter cap? Do you have it on the Transverter switch.

Terry;

Voltage IS present on both sides of R6.

I have not tried a jumper to the SG switch yet.

There IS normal drive at DRV on all bands at the indicated frequencies.

The voltage IS present at the transverter switch and at the 22uf filter cap.

Ok so pretty certain that the 210 supply is good.

Hopefully it is not the Brown wire or the Wht/Brwn broken off the Mode switch.

With the rig sitting in normal orientation you can look in from front left side rail under the Panel meter and see the Mode switch front wafer nearest the front panel. That is deck 8.

Sometimes you have to move the panel lamp red wires and tie them up and out of the way. Then you can see the Brown wire landed on lug next to an Orange wire. It will be clockwise location from Diode D2. The Orange wire goes back to FSB wire wrap on the HV Unit and provides reduced SG voltage for RTTY mode. Not concerned about it at this time.

I slip piece of spaghetti over my DMM probe tip to touch the solder lug that the Brown wire is landed on so I dont short to anything else. If you have approx 254vdc on Brown wire lug then should have it on the lugs that are heavy bare tinned jumper wired together. Count the 3rd lug counter clockwise back from cathode of D2 and should see the Wht/ Brwn wire landed on lug. Sometimes it looks like the wire is landed and soldered and it is not. Wire conductor is broken off flush at the lug, but looks like it is landed. Need to use insulated probe to gently move the wire at the lug.

If you have approx 254vdc on the heavy jumpers between the lugs (in CW and SSB modes) then should have it on PD-1 back on Final board if the Wht/ Brwn wire is good at its Mode switch lug. If you have it on PD1 should have it on PD2. If dont have it on PD2 then look at choke L4 on the Final board. Rare for it to go open, but I think you said you heard a pop sound?

Easy to temporarily jumper PD1 to PD2.

Dave:

I forgot to mention that depending on which generation TS820 you have the "White" wire from the Mode switch that is landed on the 3rd lug from the cathode of D2 diode (at the end of the bare tinned jumpered string of lugs) may be White with no colored tracer or it may be White with Brown tracer. You can tell by looking at the wire landed on PD-1. It can be plain White or a White/Brwn coming back from the Mode switch. I have never seen a PD-2 wire that was not Wht/Brwn.

Topic: 52581 Message: 52581

Yesterday I was listening to a QSO on 40m between a german and a swiss OM, both using an high-end Anan SDR. They were talking about tuning their audio spectrum and linearity for optimum on-air presence and minimum splatter. They both commented on a russian station some 10kHz lower that was disturbing their talk with its wide signal. The guy was easily heard some 10-15 kHz away, having a real horrible, wide splattering signal.

Obviously, they were able to scan the band while talking, the Anan having two independent AD-convertors. They could receive the offending station and analyze its signal for spectral purity, audio spectrum and things like that. I couldn't resist and called them to get a report on my TS-830. We had a nice long talk and they were able to tell me lots of interesting things about my signal. They congratulated me to my very clean and narrow signal, no splatter at all and excellent audio. They were even able to tell me how to adjust the compressor for the best compromise between power and clean signal. The software controlling the Anan is able to record any conversation directly to a mp3-File, so I even got a copy of our conversation per mail...

Very nice features and certainly a very interesting thing to play with, but my old Kenwood is able to do its thing after 35years of usage and putting a clean, powerful signal in the air.. what more could you ask from boat anchor? I just love these old rigs...

Terry and group.

NO voltage at the switch!

As far as insulating a probe goes, let me offer the solution I have been using for a number of years:

I take plastic body TIP jacks to which I solder various lengths of straitened heavy duty paper clips to the jack. I then cover the clip with at least two layers of shrink tubing leaving only the last app. 32 of an inch of the clip exposed. Additionally, to prevent contact with the probe itself when manipulating it I take a connector or coax end shipping cover, cut an opening in the back just large enough to slip over the rear of the pin jack snugly and slide it over the jack. This usually give sufficient coverage of the meter probe. All done with junk box parts.

I guess I will need to hunt for an open wire!

Thanks again;

Hi All: I hope (and am sure) you all can be of assistance to me: I am connecting the TS-820S to the newly acquired SM-220 station monitor with the band scope module included in it... the basic UHF radio to antenna connections are straightforward, but the IF connection to use the band scope is not, it would seem... the manual for the SM-220 indicates that I would need to connect the IF #1 jack on the back of the radio to the Pan Display input on the SM-220 AND the IF #2 output on the radio to the V-Input on the SM-220, with a modified, attenuated output on the IF Output #2 on the radio... so far so good... right? Wrong... there is but one IF out on the radio... I am obviously therefore unclear as to 1) whether such attenuation is needed, and entirely unclear as to 2) how to connect the two units, since there are simply not enough jacks to comply with the manual...

Is there something I am missing? Beside an IF out jack?

So to summarize, the questions are: Do I need to attenuate the only IF out on the TS-820S, and how does one connect the SM-220 to this radio given the shortage of outputs on the radio compared to the requested outs in the SM-220 manual?

I appreciate all your help in advance.

Greetings to all. I am new to the group and a proud new owner of a TS-830S Gold.

I am curious as to whether it does any harm to operate microphone PTT while in LSB mode with the Heater switch OFF?

While trouble-shooting worn pin connections on the microphone connector, I was intermittently triggering the PTT (also connected to a dummy load as a precaution). I understand that in that state the driver and finals are de-energized, but just wondering if there is any other circuitry that might be damaged by switching into 'transmit' mode while the tube filaments are de-energized.

Thanks in advance....great group!

Hi, Paul.

Yes, attenuation is required for the "IF 2" output RCA jack, as shown on page 10 of the SM 220 manual. However, as you note, this is not sufficient-you need an "IF 1" output as well. For that, you have to rig an "IF Sample Cable" as shown on page 20 of the SM-220 manual. This output is taken directly from the IF unit as per figure 8-6 and routed to the Remote octal 8P jack pins 1 (shield) and 2 (center conductor). You would then take the IF #1 output to the SM-220 via coax connected to an 8-prong plug into the octal Remote socket. The instructions for the IF 2 connector are also repeated on page 21, section 3. b).

Hope this helps!

From: David Boothe
Topic: 52587 Message: 52592

Paul,

It does not. The IF #1 connection is to pin 2 (otherwise unused) on the large, 8 pin octal REMOTE jack and pin 1 is a chassis ground. You can still have the linear amp keying line connected (uses pins 5 and 6 for Relay and ALC, along with a ground). See also page 15 on the TS-820 instruction manual and the circuit diagram in the service manual.

The 9 pin REMOTE VFO jack is not involved in this mod.

Safe travels.

Dave KC3CIP

Subject: Re: [Norton AntiSpam][TS-520_820_530_830] Connecting IF from TS-820S to SM-220 Station Monitor

I am traveling at the moment but will have to assume that this modification for the second IF output does not interfere with the pin settings used for the external VFO-820 which I use a great deal... Or is it the other larger jack being referred to? In which case I hope it does not interfere with the linear amp pin structure... I will look into it when I return home late tomorrow...

Have a great day,

Paul Silver

Hi, Paul.

Yes, attenuation is required for the "IF 2" output RCA jack, as shown on page 10 of the SM 220 manual. However, as you note, this is not sufficient-you need an "IF 1" output as well. For that, you have to rig an "IF Sample Cable" as shown on page 20 of the SM-220 manual. This output is taken directly from the IF unit as per figure 8-6 and routed to the Remote octal 8P jack pins 1 (shield) and 2 (center conductor). You would then take

the IF #1 output to the SM-220 via coax connected to an 8-prong plug into the octal Remote socket. The instructions for the IF 2 connector are also repeated on page 21, section 3. b).

Hope this helps!

Subject: [Norton AntiSpam][TS-520_820_530_830] Connecting IF from TS-820S to SM-220 Station Monitor

Hi All: I hope (and am sure) you all can be of assistance to me: I am connecting the TS-820S to the newly acquired SM-220 station monitor with the band scope module included in it... the basic UHF radio to antenna connections are straightforward, but the IF connection to use the band scope is not, it would seem... the manual for the SM-220 indicates that I would need to connect the IF #1 jack on the back of the radio to the Pan Display input on the SM-220 AND the IF #2 output on the radio to the V-Input on the SM-220, with a modified, attenuated output on the IF Output #2 on the radio... so far so good... right? Wrong... there is but one IF out on the radio... I am obviously therefore unclear as to 1) whether such attenuation is needed, and entirely unclear as to 2) how to connect the two units, since there are simply not enough jacks to comply with the manual...

Is there something I am missing? Beside an IF out jack?

So to summarize, the questions are: Do I need to attenuate the only IF out on the TS-820S, and how does one connect the SM-220 to this radio given the shortage of outputs on the radio compared to the requested outs in the SM-220 manual?

I appreciate all your help in advance.

Paul

I cant imagine checking continuity between DRV and SG? DRV is not landed at the Mode switch.

Any time you can power the radio it is better to take voltage readings than resistance readings. I see people taking copious resistance readings all the time in lieu of voltage readings and it bemuses me.

Have to have heck of a carbon path between the SG and Control grids on the Final Board or a short between the grid wire elements within the 6146 final tubes. Pull both of the final tubes from their sockets and then repeat voltage readings.

Also very rare to have a bad wire of any color in the harness route other than at the termination points. It is possible to have a pinched wire at mid span, but very rare unless some repair work was performed and induced the fault at that location.

Dave:

I am going to ask you one last thing and it is a repeat question. After that will let others help you.

There are two brown wires landed on the 210A wire wrap terminal post on the HV Rectifier board. The top wrap goes to the front of the radio and feeds the RF-3 molex connector on the RF board to supply SG voltage to the Driver tube. You told me that you have good RF Drive which means then that the wire wrap connection of the top Brown wire is good and the Brown wire conductor is good to RF-3 connector.

The bottom wire wrap Brown wire goes toward the rear panel and runs to the 22uf dual can filter capacitor and to the Transverter switch OFF contact. You told me that you had SG voltage to and from the Transverter switch. That means you are saying that you have approx 250vdc at the Transverter switch Movable contact and the OFF contact. The Transverter switch must be placed in the OFF position and it has a plastic lock tab to keep it there. Sometimes that lock tab has been removed.

I would repeat the voltage measurement at the Transverter Switch Movable contact and the OFF contact and I might even remove the lock if it is there and cycle the switch a few times to wipe the contacts. When the Transverter Switch is in the ON position it removes SG voltage to the Finals.

If you do indeed have good SG voltage on the Movable contact on the Transverter Switch then the next place to check for SG voltage is the PD-2 wire wrap post on the Final board. The wire landed there should be White with a Brown tracer. If you have no voltage on PD-2 then likely your model of 820 rig has the S4-5 Bandswitch contact interlock wiring. Can prove that by pulling the Cooling fan and looking to see if you have two Wht/Brwn wires coming up thru the hole in the PA cage floor and running up underneath the center of the Bandswitch decks.

Also I would observe the bandswitch coupler inside the PA cage and make sure it is turning as it should and not slipping. If it is left in the 15 mhz position (wwv/jjy) regardless of what the front panel indication is and you have the S4-5 interlock you wont have any SG voltage at PD-2.

If the S4-5 contacts are the problem I would abandon them. Nearly impossible to access to clean. I would cut the two Wht/Brwn wires inside the PA cage and pull them back down thru the hole in the floor. I would then take the White Brown wire from the Movable contact of the Transverter switch and land it on the PD-2 wire wrap post and tack solder it. OR you could butt splice and heatshrink the two Wht/Brwn leads you cut off the S4-5 switch.

This is all I can do to help you.

Good luck and be very careful taking these voltage readings.

52598. OCF Dipole Return Loss Sweep

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-07-10 23:30:07 UTC
From: wagstw46@...
Topic: 52598 Message: 52598

In response to off list questions about multi-band coax fed antennas that can be used with KW hybrids with no external matching unit ie "tuner" I have added a picture of a Return Loss Sweep of my 80 - 10 meters Off Center Fed (OCF) dipole to my website. You can view it at www.k9tw.com http://www.k9tw.com under the Photos page.

I use this antenna routinely with my TS830 and to test all models of customer KW hybrids. I use no in line antenna matching unit between the transceivers and this antenna. It is fed by approx 80 feet of RG-8X that runs to Alpha Delta antenna switches in the shack that routes it to the operating position or the test bench.

Not long ago this topic was discussed here and Trapped Verticals, Trap Dipoles, Fan Dipoles, and OCF dipoles were all mentioned as candidates for multi-band operation with no need for a "tuner" other than the Pi-network in the rig. I have used all of these antennas at one time or another and about 2 years ago built my 1st OCF. Mine is approx 135 feet long in inverted V config and has a 1/3- 2/3 split that is coax fed approx 45 feet from one end thru a good quality 4:1 current balun and a ferrite bead choke heat shrinked over the RG-8X coax just below the balun. Several other configs are in the literature that have different feed point off sets and if you dont have 135 feet of room can also make one for 40 - 10 meters that will be approx 68 feet long.

If you want to convert the Return Loss to VSWR you can use an online calculator or a conversion chart. Mini-circuits has a nice chart. You should note that my OCF version is not a good performer on 30 meters and the SWR is in the 3:1 range on 15 meters.

If you want to learn more about this antenna below is a site of a fellow who copied the Buckmaster OCF.

If you have any questions about the return loss sweep or using an OCF dipole with a KW hybrid
please contact me off the list.

52599. TS 520 qrp mod

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-07-11 01:59:47 UTC
From: bsa0791@...
Topic: 52599 Message: 52599

I have been studying the ts 520 qrp mod. Looks simple but have a few questions. I can go qrp on cw but from what I understand, this is for true low power ssb. I have a johnson thunderbolt amp that has a limit of about 20 watts to drive it, for rigs that produce more wattage, an attenuator must be used. Will this mod allow me to get the 20watt side band that I need?

With the mod, is the ssb power controlled by the front control or the resistor on the mod? What will the power range be?

Will I be better of build an attenuator?

Thanks Brian nc kb4mng

52600. Kenwood TS-820S no high voltage reading, unable to tune, no effect from LOAD knob

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-07-11 02:19:42 UTC
From: psilver@...
Topic: 52600 Message: 52600

My Kenwood TS-820S had been working like a charm for a few months, but more recently I saw the plate current max decline over time to where I could no longer get it up above 200mA while tuning... the LOAD knob appears to have no affect and the PLATE knob no longer has any impact on raising or lowering the meter reading... there is a spike at one point in the Plate knobs range, but that appears to be a spurious oscillation in the final... not good, but not related, I don't think...

Let me start at the beginning: I came home to connect the SM-220 to the system and before I did that wanted to test everything to get a baseline. The system included the radio, a TS-820S, the SP-820 speaker, the AT-230 antenna coupler, and the VFO-820... I was going to add the SM-220 station monitor. Tried tuning and found the above to be the case... no way to change the plate current with either with the LOAD knob or the PLATE knob... the DRIVE knob behaves as it should.

All the below measurements were don on 20m, for reference, but the same is true on all other bands, and is not band specific. Also all measurements are from the on-board meter... no external meter readings are used unless specifically stated.

My first step was to check the bias, just to be sure, and I reset it to 60mA, as per the manual. This went without a glitch. I also noticed at this time that the on-board meter shows no HV reading, 0 volts... Not good.

When attempting to transmit in SSB mode I key the mic and get the nominal 60mA plate current stead as a rock... no fluctuation, same as in CW mode. I get no RF reading at all when transmitting either in SSB or in CW mode. ALC and COMP meter modes show activity as usual, as if nothing was wrong, in SSB mode.Nothing in ALC or Comp in CW mode. As I said, HV shows 0 volts.

With the external Watt meter, I get minor levels of output, and the SM-220, which I inserted just to see what would happen, using only the coax through, shows modulation as normal when speaking into the keyed mic... I did not play with this further, although I can use it for other measurements if anyone thinks I can gain useful info from it... don't have a set of probes for it. Do have another oscilloscope, but am only learning how to use that... but with instruction am game to try any measurements you guys think pertinent.

I do have a spare set of finals, and a drive tube, but swapping out the drive tube had no effect... have not opened the HV cage as yet, awaiting insight from any and all of you...

Obviously I only mentioned the other gear to give you a context... I don't see any issues with the other gear that would cause this.

I am not a tech guru, but am willing to to learn and try... any help would be greatly appreciated.

Paul

From: Mike W5RKL
Topic: 52599 Message: 52601

Brian,

You will need a watt meter, preferably a peak reading watt meter.

You first tune the TS-520 transmitter for normal fully output into a 50 ohm dummy load with the QRP circuit "disconnected" from the TS-520 Remote socket. You then switch to the sideband of choice and speak into the microphone in a normal voice level while adjusting the MIC gain for a mid ALC scale indication, not to exceed the upper limit of the ALC scale.

Once the above sideband MIC gain adjustment has been completed, you connect the QRP circuit to the TS-520's 8 pin socket, the QRP circuit's "negative" terminal to pin "6" and the QRP circuit's ground to pin 1. While watching your watt meter you speak into the microphone and adjust the QRP circuit's Pot for the desired output.

There's nothing magical about the QRP circuit. The QRP circuit simply provides an operator adjustable "negative" DC voltage to the 520's "Remote ALC" (pin 6 on the 8 pin Remote socket). This negative voltage is applied to an earlier stage to control the level of RF that eventually is applied to the final amplifier, hence lower RF output. The difference between a linear amplifier's ALC voltage and the QRP circuit negative voltage is, the linear amplifier ALC voltage "varies" during transmission but the QRP circuit negative voltage is "fixed" based on the setting of the QRP circuit's "Pot".

First of all turn off the Heater switch and then STOP trying to load the radio until you have determined if you have just lost 6146 plate voltage indication (HV) or actually have no voltage on the plates.

You never want to run a Tetrode tube with no Plate voltage. The Screen grid will act as the plate and the resulting current can very quickly exceed the Screen grid dissipation and damage the tubes.

If you are not comfortable measuring the 900vdc at the anodes of the 6146 tubes inside the PA cage seek some help. Need a good VTVM or DMM with at least a 1000vdc range and good quality test leads to make that measurement.

If you proceed to make the measurement yourself suggest you down power the rig (line cord unplugged from 120vac recept) and connect the meter and then get self in clear and power the radio and observe the reading. Then down power and remove the meter and return the PA cage cover.

If you have no plate voltage failures include:
1. Failed HV filter capacitors and/or failed HV rectifier diodes.
2. Failed small VHF choke at base of large Plate choke.
3. Failed large RF plate choke
4. Bad sublimated solder at parasitic suppressors at top of Plate choke.

You also said:

"/*My first step was to check the bias, just to be sure, and I reset it
to 60mA, as per the manual. This went without a glitch.*/"

You then said:

"/*I also noticed at this time that the on-board meter shows no HV
reading, 0 volts... "

*/If you can adjust the bias pot so the IP meter in sideband transmit
indicates 60ma of idling current AND during transmitter tuning the IP
meter indicates 200ma, but the HV meter displays 0VDC in transmit, I
doubt the HV to the 6146 plates has failed. You can verify this by
measuring the HV at the 6146 plate caps using a good quality DC volt
meter (use caution when measuring this voltage). The 6146 plate voltage
in standby should be approximately +920VDC or so. If this is what you
see then the loss of HV meter indication could easily be caused by one
of the 3 HV meter resistors, R2, R3, or R4, on the HV Unit has failed,
opened or the resistance of one resistor (R2, R3, or R4) has increased
significantly.

The meter switch positions are "disabled" in receive (standby). The
meter switch positions are "enabled" during transmit by Relay RL-3 (see
the TS-820 schematic).

Group, What's the Expert's take on running CW QRP on one of the hybrids using the "carrier" control to reduce the output from full power to a low power setting? I have done this with my TS520 for many years and also with the solid state TS440s.Now I have read there are some who are opposed to this method. What's the consensus? I am not talking about SSB since I rarely run phone here. My radio is Ham Radio...CW is Real Radio

52605. Re: OCF Dipole Return Loss Sweep

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-07-11 17:20:17 UTC
From: T. Scott Griffin
Topic: 52605 Message: 52605

Thanks to Terry for a very informative posting. After trying many multi-band dipole designs, I have adopted the OCF (Off-Center Fed) dipole as my favorite. Since I didn’t have room for an 80-meter version, I built a 40-meter version which performs very well even at 25 feet suspended as an inverted Vee in the trees. As Terry says it is important to use a current balun to feed the dipole. Balun Designs sells high quality current baluns and their web site provides links to construction and performance details.

http://www.balundesigns.com/

Note that many of the assembled low cost OCF dipoles sold on eBay use cheaper voltage baluns, which is why I built my own using a Balun Designs current balun.

My OCF dipole performs well on 40, 20, and 10 meters without requiring a tuner. On 30 and 15 meters my antenna exhibits high SWR (>3:1).

52606. clarification of msg signing

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-07-11 20:09:18 UTC
From: Joseph Stiles
Topic: 52606 Message: 52606

Greeting group!
I hope we all had a safe and enjoyable 4th of July. I was gone, so the group was held together by Ellen & Jon, our two moderators...TNX.
There seems to be some confusion..why I do not know, regarding properly signing posts/msgs. Many of you already know and adhere to the group policy/rules, but for some reason, newer members fail to read the electronic copy of the group policy/rules which is automatically sent to them upon group acceptance. A great deal of time is spent dealing with this.
So, to shorten the time spent reading the policy/rules, here's an abbreviated(paraphrased) version regarding "signing": screen names, or email headers (even if they may contain a full or partial name) are NOT acceptable. Post(s)/msg(s) are to be signed(at the end of said post/msg) with your given name OR given name and call(if any). If you are a newer member still on "moderation" and, your attempted post/msg is unsigned..it will be rejected. These and all group policies/rules apply to ALL group members.
You can set up your email program to automatically add the proper signature at the end so as keep your post/msg(s) from being rejected.
Thanks for your attention..... 73 Joe

Once the transmitter is tuned for maximum output into a 50 ohm dummy load (all hams should have a 50 ohm dummy load for transmitter tuning), switching to CW, the "CAR" control is used to control power output.

Use of the QRP circuit in CW is not needed. Use of the CAR control in CW mode to control power output is correct.

Bill,
The thin flat metal strip belongs between the tube and shield. Sometimes people who don't have patience or understanding push it out of the way. Remember to discharge hv before placing hands or tools in your radio

Bill,

I believe what you are seeing is the tube shield for the driver 12BY7A. The strip is the ground for the tube shield. The strip should be inside the tube shield between the shield and the tube. This is unlikely the reason for your blown fuse.

Yes Silver Micas have relatively low Temp Coefficient (they are Positive and not NPO or negative) biggest problem is physical size. In the Hybrids they are under the Plate Load cap or between the end of it and the tank coil so not much room. They are installed like a stack of dimes that have been slipped over each other.

Today hard to find NPOs but can find COGs, but often find them in low PF values and not the higher values that we need.

Hi all!

I have two OFC antennas, an 80m as well as a 40m on opposite sides of
the QTH, both about 30 ft up.
I had the 40m antenna at about 45 ft but of course the YL had me take
both trees down...hi, hi.
The 80m antenna resonates on 80, 40, 20, 17, 12, 10m (no 15m) and the 40m
resonates on 40, 20, 15, 12, 10 and 6m (no 17m).
I used a 4:1 balun I bought on e-pay for the 80m and one from MFJ for
the 40m.
I've been using the 80m antenna for over 3 years and the 40m for over a
year w/o
any problems and never use a tuner.

Dave,

You can find new 7 pin DIN plugs on eBay rather easily by simply using eBay's search feature and a simple search phrase such as:

"7 pin DIN plug"

I found the following 7 pin DIN plug ads in "Consumer Electronics" area. This is only a small sampling of the ads offering 7 pin DIN plugs, some with cables and some without cables (plugs only).

U.S. eBay seller (Hemet California) offering 7 pin DIN plugs, free shipping, under eBay ad #371378610154.

U.S. eBay seller (El Dorado Hills, California) offering a 7 pin DIN plug, free shipping, under eBay ad #400265650159.

Here's an eBay seller from China (Shanghai China) who's offering a lot of "10" 7 pin DIN plugs for a cheap price, free shipping under eBay ad #301550236250.

A big reason some groups *require* a call sign, (Like mine: HeathKitHF_Amps, and the Kenwood TH-F6a[e] group were I mod., not because they can be modded easily, but because many people are now buying the radio to use, illegally, while camping, travelling, etc. [Don't ask me why, 'cause I don't know, but that little radio seems to be more popular for illegal use than the cheapo Chinese radios that are easily purchased EVERYWHERE!]) is so we as contributors to the group, don't knowingly support the unauthorized (and illegal) use of the HeathKit Amplifier. The call sign identifies the poster as a bona fide Amateur radio operator, and not a CB'er.

Personally, I think a call in the sig should be required in *ALL* groups that support a piece of equipment that could be modified to use illegally in bands *NOT* in the Amateur realm. Heck, some amateur radios *came* with 27 MHz (11 meters) installed from the factory! (Yaesu FT-101) The HeathKit SB series of transceivers or transmitters could easily be put on 27 MHZ with the addition of a crystal. As can most of the older hybrid radios and full tubed units.

Ok, enough of the long, run-on sentence. J

Call sign ID, to me, is *very* important

Joe – W7RKN

Mike:
I thought the 7 pin DIN's in the 830 had a slightly different pin angle (262 degrees) then the "standard" 7 pin DIN which is 270 degrees. That's why places like AES sells 7 pin DINs specific for Kenwood.

52620. Re: [TS-520_820_530_830] 7 pin din plugs

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-07-12 21:05:44 UTC
From: Mike W5RKL
Topic: 52611 Message: 52620

Pete, I wasn't aware of the difference in DIN plug pin angles. Thanks
for the update. Those looking for the 7 pin DIN plug, take note of
Pete's recommendation.

73
Mike W5RKL

52621. Hybrid Net Update (July 12, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-07-12 21:17:33 UTC
From: Mark Gilger
Topic: 52621 Message: 52621

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by me, WB0IQK. There
were only 5 stations checking in under good band conditions.

We had the following number of radios checking in.

1 running TS-520(x)
0 running TS-530(x)
0 running TS-820(x)
1 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

He was running a TS-830s with my L-4B AMP.

The Sunday net was run by me, WB0IQK. There were
14 stations checking in under poor good
conditions. We had the following number of radios checking in.

4 running TS-520(x)
2 running TS-530(x)
1 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running a TS900

The rest were running non Kenwood hybrid equipment.

He was running my TS-940s + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total = 142, Sunday☐s total = 88
December 2014, Saturday☐s net total = 92, Sunday☐s total = 86
January 2015, Saturday☐s net total = 110, Sunday☐s total = 84
February 2015, Saturday☐s net total = 103, Sunday☐s total = 98
March 2015, Saturday☐s net total =80, Sunday☐s total = 51
April 2015, Saturday☐s net total = 59, Sunday☐s total = 29
May 2015, Saturday☐s net total = 79, Sunday☐s total = 48
June 2015, Saturday☐s net total = 70, Sunday☐s total = 38
July 2015, Saturday☐s net total = 19, Sundays☐ total = 25 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

73's,
Mark, WB0IQK

52623. Re: No ALC on drive tuning.

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-07-13 12:54:38 UTC
From: carlos@...
Topic: 52406 Message: 52623

OK, finally back after field day and a dead motherboard, and I quit my job. When it rains it pours.

Well, I have the vacuum tube meter. I will need help on how to use it.
I checked the relay and it does cycle, no oxidation, all looks good, 12vdc cycles it just fine. I connected the mic and with my TS480 at same freq and on a piece of coax for antenna on it. When I key down and talk into the mic I can hear it in my TS-480 and the main tubes light up nice and bright when I allow key down for a few seconds.

So thats about where I am now.

Thanks
Carlos

Good morning, I need a good IF board. I believe a 830S in need of repair. It was modified with some holes drilled in error board administrator some wires horribly served in around con 9. The board is useless. I cannot repair it. Much damage to the traces. Whom more have a great board for sale?
Thanks, 73, K5HFG, Don

Any one know where I can pick up an 8 pin octal remote jack plug that fits the jack on the back of the TS-820S? The plug as described by David below?

Have a great day,
Paul N1PSX

52634. Two problems with TS-830S: NB and notch filter

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-07-14 08:52:52 UTC
From: Martin Jangowski
Topic: 52634 Message: 52634

Hi folks,

my TS-830S works mostly fine and is a joy to use. However, two small things could be better:

- the noise blanker has no effect, regardless of adjustment, and
- the notch-filter is not working, too.

I set the noise blanker according to step #22 at the SM (adjusting AF board T1/T2 to minimum@TP4), but can not hear any effect on the signal. You can often hear signals similar to the "woodpecker" of the 1980s at 20m, and the NB should be made to minimize exactly this signal... but no effect.

The notch-filter is problematic, too. I'm unable to get any notch while adjusting L10 and VR1@IF-board. Is there a method to visualize the adjustment? I tried to set L10 to a middle level and turning VR1 and repeat this several times with small changes @ L10, but got no effect. Is this a very difficult adjustment or is something plain not working?

Thanks for your help,

Martin DB2MJ

My TS520 noise blanker was the type to reduce puse like ignition noise and did it well, had some effect on power line insulator arcing noise . Turning it on while listening to a normal CW or SSB signal, with out any ignition noise going on, sure should not have any effect on what you heard. Not sure if the 830s had any different NB circuits. My radio is Ham Radio...CW is Real Radio

I set the noise blanker according to step #22 at the SM (adjusting AF board T1/T2 to minimum@TP4), but can not hear any effect on the signal. You can often hear signals similar to the "woodpecker" of the 1980s at 20m, and the NB should be made to minimize exactly this signal... but no effect.

The notch-filter is problematic, too. I'm unable to get any notch while adjusting L10 and VR1@IF-board. Is there a method to visualize the adjustment? I tried to set L10 to a middle level and turning VR1 and repeat this several times with small changes @ L10, but got no effect. Is this a very difficult adjustment or is something plain not working?

Thanks for your help,

Martin DB2MJ

52637. How Many Used Kenwood Hybrid Rig During Field Day?

Yahoo group: TS-520_820_530_830 (2015 — 2016)

I am just wondering how many amateur radio operators here used their Kenwood Hybrid Rigs during this last ARRL/CRRL Field Day? I used my Kenwood TS-820S for PSK 31 on 20 meters at Lakeside Amateur Radio Club's Field Day site.(Headquarters of Lakeside Fire Protection District, Lakeside, CA). It worked well. Another ham brought his Kenwood TS-830S to use for 40 meter phone as he had done in previous years, but it was found during setup that it would not transmit and was replaced with an all solid state rig. What experiences did all of you have with your Kenwood Hybrid Rig(s) during Field Day?

Okay... so have High Voltage... on board meter showing 800 volts when transmission is keyed... have nominal idle plate current at 60mA...

Tuning in the following fashion: Turn meter to ALC, set mode to TUN... Set Carrier to 6, or about 1:00 o'clock... use DRIVE knob to peak the ALC meter to maximum (all the way to the right, but not pinned)

Then change meter to IP, set mode to CW, and using the Send switch, try to set plate current to about 200mA using PLATE and LOAD knobs...

Nothing happens... rotating either of these knobs does absolutely nothing, except for the occasional spurious peak, which I am now well aware of needing to avoid, thanks Dave...

Already swapped out the drive tube with a known good one... no impact... have not swapped out the finals, although I do have known good ones...

Where to go from here?

52641. RE: [TS-520_820_530_830] Kenwood TS-820S no high voltage reading, unable to tune, no effect from LOAD knob

Something I have used very successfully in the past: If trying to find solder cracks/breaks in a PCB, and it is out of the case, I use a dye and developer. I just spray the dye on the foil side of the board, wipe the excess off, then spray with the developer (Nothing more than a white powder) If there are cracks, they will show up instantly. The dye is electrically non-conductive, so after noting any cracks, I blow (clean) off the developer, then re-solder the bad spots and I am good to go. A bit of work, but any cracks are found quickly and easily and, in the end, saves a lot of heartache of pulling and reinstalling a board, only to have it continually fail, due to an unseen solder break.

Subject: Re: [TS-520_820_530_830] Kenwood TS-820S no high voltage reading, unable to tune, no effect from LOAD knob

Paul,

Get a bright light...I use an LED penlight...and a magnifying glass. Inspect the driver tube socket solder joints/connections on the foil side of the board. They are easily viewed...look for small circular cracks around the pin mounting holes/solder pads. Over many years of operation these joints are known to crack and cause problems....fine the night before...then nothing....just a thought

I previously tried to help you and wasnt successful so here is one last effort. Why in the world are you trying different Driver tubes or looking for dirty Driver tube socket to pin interface or cracked solder at the Driver tube scoket ????

What does being able to peak the ALC indication in Tune Mode mean to anyone???

It means you have sufficient RF drive voltage swing (from the plate circuit of the Driver tube) at the Control grids of the 6146 Final tubes to overcome the DC offset established by the operating bias voltage to cause the control grids to be positive with respect to the cathode and a very small grid current to flow (around 40ua). When that happens the ALC amp circuit bucks the ALC bus voltage and reduces the control voltage from its normal RF-1 level. The ALC meter FET sees this and drives the panel meter up scale. This allows you to peak the ALC reading which means you have tuned the Driver Tube input and output LC circuits to resonance. At resonance you are presenting highest RF voltage swing at the 6146 final tube control grids.

Based on what you are reporting your Driver stage is working fine.

Having 800 or 900 volts on the HV board is meaningless. I tried to direct you to proper place to measure and gave you some safety precautions to accomplish that. The 6146 Final tubes like to have 900vdc at the end of each parasitic suppressor and on to the metal plate cap under each phenolic cap and on to of each final tube. Always measure at the top of the main RF plate choke as previously advised. If you dont know what sublimated solder connections look like then measure on the bare wire of the parasitic suppressors close to each phenolic cap.

Also, you are skipping a step. Before switching to CW mode while still in Tune mode you place the panel meter in the IP position and flip to Send and dip the plate current with the Plate (Tune or Tank) capacitor. This is tuning the Pi-network to resonance. Inexperienced people should never do that in CW mode.

No where in you manual does it tell you to adjust the Plate Load and Plate Tune for 200ma IP. Where does it state that?

After you dip the IP in Tune you place the panel meter in RF position and place mode switch to CW and you flip to Send and alternately adjust the Plate Load and Plate Tune capacitors for maximum indicated relative power. None of the meter scales mean anything just adjust for maximum which is maximum RF voltage at the SO-239. Into a dummy load that will be approx 71 rf volts at 100 watts. Some people do a combination of dip and load and then finish off using the RF relative power position, but if you have limited experience literally follow the manual steps.

When done peaking the RF relative power you can check IP and it should be approx 200ma. Dont worry if it is 10 or 20 ma higher as you will be using low duty cycle modes (CW and SSB) and wont exceed plate dissipation.

I would check all the DC voltages on the 6146 final tubes at the tube socket pins on the Final board. Measure the Screen Grid voltage and the Operating Bias voltage. Based on 60ma resting plate current and your good ALC indication it is likely that you have the correct dc voltages, but very easy to confirm that.

When in Tune mode and the meter in IP and flip to Send and you cant dip the plate current with the Plate Tune cap then it is possible that the shaft coupler has come loose and you are not actually turning the capacitor shaft or you may have a bad Plate block cap.

Quit goofing around with the Driver stage!

Topic: 52600 Message: 52644

I forgot to mention that with a loose Plate Tune cap coupler or an open Plate Block Cap you should see very high plate current when you go to CW mode and flip to Send. Only thing either of those two failures should produce is the inability to dip that plate current with the Plate Tune capacitor.

You are saying you see nothing over a nominal 60ma and that sure sounds like you have operating bias and screen grid voltage at the 6146 tube socket pins and no anode voltage.

I also forgot to ask if you see this nominal 60ma when you flip to Send in either LSB or USB modes? If not, and only see it in CW mode then failure has to be no 900vdc at the anodes of the 6146 final tubes.

If I am wrong then a public admission is in order and it wont be the first or last time.

OK goofing or fooling around with the Driver tube was poor choice of words. Meant no disrespect to you.

Guess I am just frustrated as I have explained how RF drive is generated and what ALC is so many times I have lost count. For some reason it just wont stick so I wonder sometimes why I spend the time and energy.

I will move on and let other well meaning folks with much more patience help you. Will be very interested to learn what you find. Please make sure you post the findings and corrective action so we can all learn from it.

From: Greg W.
Topic: 52646 Message: 52646

Good evening, all!

I've had my TS-530S for a while now, and I love it. As an artifact of where I live, the noise floor is pretty high even when I eliminate all of the RF interference in my top floor apartment (usually above S7 on 20m).

Nonetheless, I recently found that when I touch the outside of the radio's case (by the leather strap, for instance) with my hand, the noise floor drops by maybe S-0.5. It doesn't electrically shock me or anything, but is this a problem or something I can fix? Or is it just part of having a radio of that age?

Thanks and 73!

Greg

Greg:

Do you have a voltmeter? If so measure the cabinet to the safety ground pin on your 120vac receptable. Get on one of the screws and not the painted surface. Measure it with the plug reversed. Plug it in which ever way produces the lowest voltage on the cabinet. May range from 35 to 55 vac. See if reversing the line cord changes the hand effect on the cabinet. Is the lock nut on the SO-239 connector tight? It can be snugged with a 17mm 12 point box end wrench. Dont use a pair of channel locks.

Check the continuity of the shield braid at your PL-259 connector. You can do that by just inserting the PL259 center pin into the SO-239 and note the S-meter reading and then insert the PL259 in further until the body makes contact. S-meter level should drop.

Do you have a safety ground wire connected to the ground stud on the rigs rear panel. If not do so.

Terry: I fully grasp your frustration, but the latter posts were not mine... I did the drive tube on my own before posting this question to this discussion... I have ceased playing with the drive section... others, including my Elmer, have indicated that perhaps the T/R relay may be at fault...

My error was in describing the problem as also having no HV... in fact I found that I had the Carrier set slightly too high, somehow, and when I turned it down from setting at 7 to 6, or from 2 o'clock to 6 o'clock, I had full control of setting the meter to maximum deflection... that is why I said the drive is okay... perhaps I was wrong... but it certainly appears okay... I also know that you have told me how and where to measure the high voltage, but as I did not own a meter that could go above 300 volts, I could not do that... I have since ordered a meter capable of measuring the voltage up to 1000 volts, but have not yet received it... when I do I will be certain to make all the measurements you suggest...

My task today will be to clean the T/R relay... since I can do that without otherwise causing any harm, and I dont need the high voltage meter to do it...

Beyond that, your posts have been extremely helpful, and I hope you continue to guide me on this repair. As I have said, I am not a repair guru of any sort, and this is my first non-solid state radio, so I am again a novice with this.

I appreciate your input, and that of others, and look forward to getting the radio on the air again, what ever learning curve it take on my part.

Thanks to all of you for your comments, I will keep you posted as to my progress.

Paul:

No disrespect to your Elmer or others who suggest the TR relay is the problem. Not very likely.

You can attempt to load these radios with nothing connected to the SO-239 connector and you will have lots of plate current and be able to dip it with the Plate Tune capacitor just as if it was connected to a 50 ohm dummy load. An open in your antenna system (including a high resistance contact in the TR relay) can fool you into thinking your are loading the radio. This is one of the reasons I recommend an external wattmeter to new folks. Too many keystrokes to explain why and how this works.

I am not advising you to try loading with no load on the radio as it is possible to have a Plate load cap arc over. In fact I cant advise you to do any more loading attempts until you confirm that you have 900vdc on the plates of both final tubes.

You did not answer my question if you could set resting plate current in either LSB or USB modes. You do that with heaters on and the mic gain turned all the way down. You dont set resting plate current in CW mode. Your manual provides Table 2 and Table 3 with the control pre-set positions for getting ready to load and you will see that radio is to be placed in SSB mode to set the resting plate current. There is a reason for this, but again too many keystrokes.

It wont hurt to pull and clean the TR relay, but if what you are reporting is accurate and/or if I understand what you are reporting then the TR relay is not the problem. Just be very careful not to bend the movable leafs during the cleaning operation.

Lastly, no such thing as having the CAR Level Pot too high when peaking the Drive Control unless the ALC meter indication is pegged FSD against the stop. Pretty hard to peak it when you cant see the peak. So simply back the CAR level down to get it on scale where you can see your peak. You are not setting any level of grid current and cant hurt anything by peaking outside the black ALC printed scale. Like RF relative power none of the meter scales mean anything when peaking the Drive in Tune mode.

As I stated I really have pretty much exhausted any help I can provide. This long distance troubleshooting isnt easy. Mike and others who understand how a grid driven tetrode PA works and how the 900vdc supply is converted to RF will be able to help you.

Just be very careful measuring the anode voltage when you get that new meter.

My first attempt at FD was in 1968 in Washington state, I was in the Navy. I operated with a friend back then, W7ND (now an SK even though the call sign has since been reassigned), using a Swan 350. The last time I operated FD was in 1982 and I operated CW using a Hallicafters HT-32 xmtr and SX-101 rcvr and a Heathkit HD-10 keyer. I was stationed at the Fleet Training Group, Guantanamo Bay, Cuba (June 1980 to June 1983), call sign back then for FD was KG4FD. Had the same problem as everyone else typically had when operating in close proximity to other stations during FD. I doubt the KW hybrids are immune to RF from stations operating in close proximity during FD.

The only KW hybrid that I would use at Field Day would be a TS-520S or SE. Both have separate receiver antenna jacks and switches. You can then put up a separate receiving antenna at your field day site and place a "Front End Protector" in series and have good chance of not losing RF amp mosfet in front end. Here is an example of a passive front end protector.

https://www.arraysolutions.com/Products/ARRAY%20QST.pdf
https://www.arraysolutions.com/Products/ARRAY%20QST.pdf

You can also find them that use fast switching relays for transceiver use and a common antenna. Here is an example of a homebrew one.

Well, after cleaning the contacts of the screen current switch on the back, replacing the Antenna relay which was fairly well pitted in the contacts, and cleaning the T/R relay, the radio is working again... not sure which of these things made the difference... likely it was the switch cleaning... but in any event, without further ado, it seems to be working correctly, and tunes up nicely... I wont go into the tuning process, but I did as per the manual Terry... perhaps my wording was poor due to my naivety in regard to such technical issuers as plate current and grid voltage... but I will say that I learned a great deal in the process, and continue to learn from many of you... Since I was unable to measure certain voltages given my lack of adequate instrumentation, (I have since ordered proper instrumentation, including a VTVM, a Frequency counter, and a Signal Generator, as well as a proper ranging Volt Ohm mA meter... an I have had the pleasure of talking to a couple of you off group, and one has even bent over far enough backward to help me by building me a RF probe for my old Oscilloscope... for all of that I thank you all...

I will be modifying the radio to work with the SM-220 station monitor properly once I shake it down to be sure it is in fact fixed for the long run... some of you have already aided me in that process... but while I am at that task, I will have the radio open again, and will by then have the instruments needed for the measurements several of you have requested... for my own benefit, and for the record in the group here, I will take those measurements and post them so that we can see what the radio is actually doing...

Of course, if the fix is temporary, I will never the less have the proper instruments, and will bea able to provide such data if the time comes to enact a more permanent solution...

Thanks again all, I really appreciate your assistance and patience with a hybrid and tube novice.

Of course, I went out and bought a Drake TR-4C which will be coming along with the new instruments... so I am really going to sink my teeth into the tube beast... hopefully on my own schedule and not its... !&^(&⋆$^^@#

Thanks,

Paul

52656. Tuning 530S for Low Power/PSK31

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-07-18 14:26:25 UTC
From: KD9BQO - James Brantley
Topic: 52656 Message: 52656

Hello all, I've had my 530 for about 3 months or so now and have really been enjoying it. I get great reports on SSB phone and recently made my first CW contact. I'm becoming increasingly interested in the digital modes and have got my 530 & a SIgnalink copying flawlessly.

Now on to my question. I've read various opinions and methods to tune for low power as in for PSK communications. What is the proper way to go about this on the 530?

Thanks in advance for your replies.

KD9BQO

From: Mike W5RKL
Topic: 52656 Message: 52658

James,

Tune your 530 up as you normally would, into a 50 ohm dummy load for full output power. Once the transmitter is properly tuned, make mic control adjustments for a normal sideband voice peak ALC indication (mid ALC scale but not to exceed the top of the ALC scale) when speaking into the microphone in a normal voice. Once this is completed, do not adjust the MIC gain any further.

At this stage, you adjust your sound card digital mode transmit audio levels to minimum then key the TS-530 transmitter in sideband and adjust the sound card transmit audio so the ALC meter just "flickers" above zero then adjust the sound card transmit audio "down" so the ALC meter just rest at zero. You do not want any ALC indicated during digital mode transmit.

Now, with the transmitter still keyed, the QRP circuit connected to the rear REMOTE DIN socket, and with digital transmit audio applied ot the TS-530 in sideband, adjust the QRP circuit for the desired RF output.

I attached the QRP circuit's pdf file to this response and sent this response to the group and your private email address. The circuit draws a very low current, less than 1ma, so the 9 volt battery should last a long time.

73

Paul

If you want to know which of the items you worked on was the root cause pretty simple tests you can perform.

Pull the Ant TR relay from under its shield can and try loading the radio. You will see that with no load connected to the output of the Pi network you will have plenty of plate current (Ip) and will be able to vary it with the Plate Load and Plate Tune capacitors. Dont do this for long time as it presents a high VSWR which means higher than normal RF voltage across the Plate Load capacitor. Actually you will have a load connected just not 50 ohms. It will be seeing the 11k ohm RF detector circuit divider string.

Next put the Ant relay back in place and lift the Red lead off the Screen Grid switch and place something on the order of a 470K resistor in series between it and the switch terminal. This will simulate very high switch contact reistance. Based on some rough calcs using typical screen grid current you should see something on the order of 50ma to 70ma Ip, but will not be able to load the radio. You will have good RF drive and resultant ALC indication as the Driver tube screen grid supply does not pass thru the SG switch. If you have a 1 meg pot that should allow you to dial in exactly the current levels you were seeing.

Loss of anode voltage will produce similar results as very low screen grid voltage. I have seen rigs with no screen grid voltage due to a broken brown or red wire at the SG switch, but never saw one that had switch contact resistance so high that produced the Ip results that you reported.

I have my personal TS820S here but have the covers on it. If you are reluctant or have no burning desire to understand what was going on I can remove covers and perform testing when I get some time, but better for you to observe it.

Lastly, you do not need an RF probe with your O-scope. Your O-scope is an RF voltmeter. You will need it with your VTVM or DMM (preferably the VTVM).

I couldnt sleep at nite not knowing what the root cause was!

Have fun and be careful.

Terry K9TW

52662. Re: Kenwood TS-820S no high voltage reading, unable to tune, no effect from LOAD knob

Yahoo group: TS-520_820_530_830 (2015 — 2016)

Paul:

I forgot to mention that anytime you do see loss of HV on the rigs panel meter DO NOT assume it is a loss of indication problem. Because you see an Ip reading it does not mean you have plate voltage on the finals. You must validate that. Always shut off the heaters so you dont have any cathode emission and then stop trying to load until you have confirmed that it really is just a loss of indication and the way to do that is as stated here several times on this thread to measure the 900vdc at the end of each parasitic suppressor off the top of the RF plate choke in the PA cage. Because you have it on the HV filter caps or the HV board does not mean you have it on the anodes of the final tubes. Common ways to lose it include open small VHF choke, open RF plate choke, sublimated solder at parasitic suppressors.

If you have no 900vdc at the anodes of the S2001A or 6146B/W tubes that 50ma to 60 ma IP that you are seeing on your panel meter is 50ma to 60 ma of Screen Grid current and that is not good on the tubes. Maximum screen grid dissipation is 3 watts. If screen grid voltage is 215vdc key down then 3w/215vdc = 14ma x 2 tubes = 28ma absolute maximum screen grid current limitation. So you can see with no anode voltage and 50 to 60 ma indicated Ip you are nearly double the 3 watts dissipation rating for the screen grids (215vdc x .028 = 6 watts). Easy to pretty quickly damage the final tubes with repeated loading attempts in this state. Note: Some finals can withstand this better than others. I have found that the S2001A screen grids can survive repeated loading attempts with loss of anode voltage better than various brands of 6146B tubes. I have never seen a S2001A data sheet so I dont know what the max SG dissipation is, but doubt that it would be much more than 3 watts? If anyone has one would be welcome addition to the Files section.

On the TS-820S rig in CW mode at 100 watts RF output and 200ma Ip the screen grid current will be very close to 16ma or 8 ma per tube (I have measured it). Assume SG voltage at 215vdc then 215 x .008 = 1.7 watts. Well within the maximum 3 watts dissipation.

The whole point of this is dont assume. Always measure. Without measurement only making educated guesses and can get fooled. It sounds like you are willing to invest a little money into modest amount of test gear and will soon be in position to measure both DC and RF signal voltages. Suggest you get some large schematics to mark up or start keeping a note book and record your as found readings for future reference.

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by me, WB0IQK. There
were only 7 stations checking in under good band conditions.

We had the following number of radios checking in.

1 running TS-520(x)
0 running TS-530(x)
0 running TS-820(x)
5 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

He was running a TS-830s with my L-4B AMP.

The Sunday net was run by me, WB0IQK. There were
19 stations checking in under poor good
conditions. We had the following number of radios checking in.

4 running TS-520(x)
2 running TS-530(x)
2 running TS-820(x)
5 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running a TS900

The rest were running non Kenwood hybrid equipment.

He was running my TS-940s + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total = 142, Sunday☐s total = 88
December 2014, Saturday☐s net total = 92, Sunday☐s total = 86
January 2015, Saturday☐s net total = 110, Sunday☐s total = 84
February 2015, Saturday☐s net total = 103, Sunday☐s total = 98
March 2015, Saturday☐s net total =80, Sunday☐s total = 51
April 2015, Saturday☐s net total = 59, Sunday☐s total = 29
May 2015, Saturday☐s net total = 79, Sunday☐s total = 48
June 2015, Saturday☐s net total = 70, Sunday☐s total = 38
July 2015, Saturday☐s net total = 26, Sundays☐ total = 44 (Month to date)

I recently sold my last TS-830S and have the following parts for sale:

1. RF Board - No slug in 160M RF Coil
2. RF Colis for 3.5 and 10.1Mhz Bands
3. Plate Choke and Tube Caps assembly
4. Knurled Rings (2) and Flat washers (2) (for antenna jack)
...and...

K4EAA parts kits (purchased new-never used:
HV-150B HV Kit
FR-100 Final Cage Kit
RK-53 Resistor Kit
PL4 Lamps (Qty 2)

Pictures of these parts can be seen at my web site www.vo1hp.ca under the FOR SALE Menu.
Please reply off list to fdavis@nfld.net or invl160@gmail.com

Asking $120US plus postage for the full kit only.

Topic: 52564 Message: 52666

More information is needed.

The possibility list is endless.
1. Shorted final tube.
2. Power supply issue.
3. high SWR (antenna , cable, connectors, in-line device.....)
4. Bias for finals grossly wrong or non-existent.
5. Mis-tuned final.
6. shorted screen resistor (not-likely, but....)
7. Stuck relay
8. Coupling cap from driver to finals is leaky or shorted.
9. Final components (output coupling cap, plate choke, choke bypass cap, etc.) are damaged or out of spec.

This is just for starters.

So,

1. what frequency?
2. what was Ip (plate current?)
3. Tuning procedure used?
4. antenna ?
5. Other problems with radio in past?
6. Did you do any further procedures, such as replace the fuse and try a dummy load? What happened? I don't suggest you replace the fuse and try again, that can cause more damage than what may already have occurred. But if you did, what was the result?

I have much doubt that the fan is the problem.

If you are not familiar with fixing a tube transceiver, I suggest finding someone who is, and have them look at it and assist you. You are in a high voltage (800+) area that can be quite dangerous if you are not familiar with this equipment. I don't know your capabilities so please do not take offense.

Hello All,

This is Walter Dilley, kd7dny. I purchased Bob's entire inventory of Kenwood Hybrid Parts.
My plan is to continue to bring parts to our Hybrid community just as Bob has done all these years. Right now, all those parts are in several dozen boxes piled high on my living room floor. It will take some time to make sense of it all, compounded by my still working a full-time job. However, don't hesitate to ask/order as it will force me to start the sorting process...

Bob,
It was great to see you in person and to meet your family. They were instrumental in loading my mini-van so precisely that nothing was broken during the 1,000 mile return trip and it all fit in, too! I wish you many happy miles in your new RV and opportunities to go fishing with the grand kids. Sweet!

Sincerely,
Walter, kd7dny

Hi all,
My newly acquired TS830S suddenly died, and a little investigation showed that the low voltages(9V & 3.6V) after Q34 on the AF board were down to about 0.5V.
Before Q34 the 14V (14A) is present, although measuring just over 18V, which I put down to there being no load. (?)
Has anyone seen this before, or have any ideas? No smoke seems to have been let out of anywhere that my eyes and nose can detect.

Thanks in advance for any help that anyone may offer.

David: What is the regulated 12vdc reading? You have two series pass linear regulators. Need to determine if you have regulated 12vdc available at Collector of Q34. There is a wire wrap terminal post.

Around 18 volts or higher is normal. You have a full wave bridge feeding a capacitor input filter. 14 x 1.414 = 19.6.

Not easy to troubleshoot due to component density and devices with short leads.

Could be bad zener reference diode and could be bad series pass transistor. Not very often find a failure with the comparitor transistors.

Before Q34 the 14V (14A) is present, although measuring just over 18V,
which I put down to there being no load. (?)
Has anyone seen this before, or have any ideas? No smoke seems to have
been let out of anywhere that my eyes and nose can detect.

Thanks in advance for any help that anyone may offer.
David VE7DVJ

Question: internal wiring to the octal socket... what sort of wire do you guys recommend? I realize this is a seemingly silly question from a novice technician, but to me it seems important... I am about ready to do the mods to make this happen, having received the octal plug yesterday... I have the resistors, etc. and my rig is working again... had an issue with the relays not contacting properly, and the SG switch not making good contact... but those issues are now resolved.

So, next is the mods for the SM-220...

Wire size, type, etc.?

Paul,
glad ur rig back working. You can have Yahoo email automatically add a signature.
  From the Yahoo email main screen(this one), look to the far right, put cursor over the "cog" shape...a drop down menu should appear...click "settings," click "writing email," look at the screen now...you should now be able to pick your font type & size...then enter your text signature...(name & call preferred)...click "save." Now when you send an email to the group...the signature you put in the box should now be at the bottom of the blank email screen...and will be sent along with the email...just as shown ...takes away the senior moments

Hello...

I have a TS-830S that I let my dad borrow. We put up a 40m dipole, and in our haste to get the radio going didn't properly tune the antenna. I used my bird watt meter and had over 100 watts out and about 20 watts reflected. I know , I know...should have fixed that. We made a contact, the bands were crap and thought all was good. A couple days later, my dad calls me, tells me he was just calling CQ and BAM!! He hears a loud cracking sound. My first thought is one of the filter caps for the HV, but I had replaced those not even 4 years ago, and we have HV. I got the radio home, don't see any damaged components, smell nothing either. I go to the first tune up step checking the tube bias, and the normal 60mA reading is now pegged on the meter. So I know something is really messed up. Does anyone have any words of wisdom as to where I should be looking for a problem? I do have spare tubes, but haven't tried anything yet until I hear back from someone who knows way more about this than I do. As a side note, I have replaced the cathode resistors, the choke and cap in the tube area and the HV caps. All of that was done at the same time and the parts were purchased from Ken K4EAA. Any help would be greatly appreciated as the old man is bugging me badly to get on the air, hi hi.

Dave,
Was this done now or 4-years ago?
The problem could be a tube(s). If they arced, the cathode resistors
need replacement again as well as new tubes.

Thanks Terry, very helpful. Measured voltages on Q34 are:
E:18.85
B:18.25
C:0.438 (the 12V line)

The Base looks too high according to the circuit I have, but not sure why at this point.

Q34 looks like it has been replaced at some time previously with an equivalent (?) ECG153, but I suspect that has failed too. Seems the problem is a recurring one.

Thanks for any further insight. I have the board swung out to access the foil side, so can make any other measurements.

Dave,
Check value of the cathode resistors again...should be 5 ohms (+/- tolerance) to ground...closer to 5 ohms..the better. As Jan stated...a tube may have arced. k4eaa's kits use good parts..but even then...things happen. the metal film resistors do not usually fail like the carbon comp ones...I bet if you look real close..you'll see a dark spot..or line...at the "waist" of the resistor..may be hidden by the color code bands. You may also have damaged one or both of your final amp tubes.

It's likely to be the screen and grid resistors on the finals board.

They're designed to blow before anything else and make a lovely loud crack when they go.

Easy enough to replace. Ken K4EAA's page has s good description of what you need to do (plus good stock of high quality repayments).

Hello om's

I am a new member on this group. And I am started again after a break of 7 years with the radio hobby again.
I buy a old Kenwood TS-515. Very nice radio. Bud I have one little problem.
After a time (20 - 30 Min.) the S meter go to zero.

When I remove V2 on the IF-board and wait some seconds and place it back.
The S meter is function okay. Till some time and it is back on zero..
It looks like there is something wrong whit the ACG?

I trade the tubes. Renew most of the resistors. Some resistors have risen 30% in value.
Bud nothings help.
I hope some of you know what this problem is.

And second I search for a CW filter for the TS-515 FBB-332-1 ??
I hope someone can help my also with this item.

Regards Gerrit PA1MT

Gerrit,
Yes, it could be a weak tube, and/or some of the filament current
limiting resistors (if any, I don't have a schematic on the 515 yet)
have gone high in resistance, and you mentioned that you already found
some others that were bad.

David

It looks like you have sufficient forward bias on Q34 so I would say it is open. If you have incircuit transistor tester could test it with board rolled over. If not then probably best to go ahead and remove it and bench test. Even simple ohms meter diode junction test should reveal its state.

Today the sub for a 2SA473Y would be a NTE153.

If you have a bench supply can apply 12vdc to the 12vdc terminal post and see if radio will come alive. If no bench supply then couple of 6 volt lantern batteries. Could then measure the dc current to see if it looks abnormal. The ECG153 is good for 4 amps and wont be anywhere near that level on the 9vdc and 12vdc busses combined in normal operation.

Topic: 52587 Message: 52694

Hi Thnaks for reply my topic!
The AUX band in TS-830s share with same VCO in 10m band,I thinkthe AUX band for 11m band use. that means we can not use the VCO in 6m too. we need add a extra VCO and a 45.5MHz oscillator for 6m receicving and transmitting, certainly ,the extra coils for 6m resonant tank are needed.we still need a switch the control the divider in PLL unit, so we can cover all 6m band (50-54Mhz).
So I do not think cover 6m band in receiver of TS-830s is a problem, the challenge in transmitter.

Do you have an Audio Generator and an O-scope? If not best you can do is plug and unplug Molex Connectors and/or swap PC boards.

Regards Molex connectors often can fix the problem with careful plug and unplug to wipe the pins. The other common fault is a bad lead wire crimp or a broken wedge shaped spring contact floating inside the Molex connector body. This is a common TS820 build quality issue. You can gently grasp the lead wire where it enters the connector body with small needle nose pliers and pull and push on it and often get the function to temporarily work.

With an Audio Generator and O-scope or even just your voice into the Mic and O-scope you can start at VOX at Molex Conn IF-4 Pin 8 at the IF board and confirm you have output from the IF board. Then move to wiper of VOX gain pot , then move to MV terminal at FIX board, and so on. Are you certain that the FIX board is seeing a good ground at VS Pin 2 on Molex Conn FIX 3?

Troubleshooting audio is one of the easier tasks if you have some modest test gear. Swapping boards is easier and faster than troubleshooting to the component level, but about 90% of time it is a problem with a bad connection and not a failed active device.

Terry K9TW

52700. TS-820S DG-1 display out

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-07-26 05:05:45 UTC
From: manderson852@...
Topic: 52700 Message: 52700

I have read the replacement display unit is X54-1310-00. I'm wondering if anyone has had to replace this or if there is way to operate the radio without it.

Thanks,
/Mike

The TS-820S will operate without the digital display.

There are 2 models of the TS-820 transceiver

1. TS-820 without the digital display
2. TS-820S with the digital displya

If you have the TS-820S operator's manual, turn to page 42 and you will see the location of the digital display components/assemblies.

Turn to page 35 in the TS-820S operator's manual which shows how to "install" the digital display. All you have to do to remove the digital display is to reverse the "installation" procedure. Pay attention and note the "edge connector" found on the bottom of the Counter Assembly (below the chassis) as show on page 35 Fig 27(C). Don't forget to remove this connector. I would disconnect the bottom edge connector first then disconnect the Counter Assembly, loosen the Counter Assembly mounting screws, then remove the Counter Assembly. The other items can be removed next.

Check to ensure you did not disconnect or cause problems with other assembly plugs, it's easy to do, before you power up the 820. Once the digital display components/assemblies have been removed, the TS-820S will now be a TS-820 and should work fine without the digital display.

Mike,
Good news and bad.
Your TS-820S will work just fine without a functioning DG-1 and it's display...that's what the TS-820 is...just no digital readout. The part you stated it no longer available from Kenwood..or any other place...except for someone who parts out rigs. there is a company "Almost All Digital Electronics," that makes a new unit for various rigs...including the 820(S) At last check, he's off-line due to illness and is not taking orders(info good as of this morning)

The display tube very rarely goes out...but as in all things electronic..it can. The MOST common problem is with the DG-1 unit itself. You should unplug rig from power...and remove the DG-1 unit. Perform the procedures outlined in Service Bulletins #26 & #53. This involves(as in the case of #26) cleaning the "through pins" between the two circuit boards inside the DG-1 and/or resoldering the "through holes" on the counter board (X-54-1160-00) There are...I think 18 or so...you will need a low wattage fine tip soldering iron, small diameter rosin core solder, some small pieces of wire...(clipped ends of resistors..and the like work just fine) small cutters...good light and some magnification. Also check the 5V AVR unit(x-43-1220-00) for proper voltage (5 v) It's right next to the DG-1 unit..(has the silver heatsink)

Mike,
You do not have to remove them, just unplug the connector(s). One on the underside of the DG-1 unit...and the one on the 5V AVR..you can leave the display tube connected

Also, remember to properly sign your post(s) per group policy: at a minimum...your name

52705. Hybrid Net Update (July 26, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-07-26 21:56:27 UTC
From: Mark Gilger
Topic: 52705 Message: 52705

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

There was no Saturday net as Jimmy, WB2KNR and
myself, WB0IQK were not able to run it due to
family commitments. I will be here next week.

The Sunday net was run by me, WB0IQK. There were
12 stations checking in under poor good
conditions. We had the following number of radios checking in.

3 running TS-520(x)
1 running TS-530(x)
1 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running a TS900

The rest were running non Kenwood hybrid equipment.

He was running my TS-830s + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total = 142, Sunday☐s total = 88
December 2014, Saturday☐s net total = 92, Sunday☐s total = 86
January 2015, Saturday☐s net total = 110, Sunday☐s total = 84
February 2015, Saturday☐s net total = 103, Sunday☐s total = 98
March 2015, Saturday☐s net total =80, Sunday☐s total = 51
April 2015, Saturday☐s net total = 59, Sunday☐s total = 29
May 2015, Saturday☐s net total = 79, Sunday☐s total = 48
June 2015, Saturday☐s net total = 70, Sunday☐s total = 38
July 2015, Saturday☐s net total = 26, Sundays☐ total = 56 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

David:

If you cant find an 830 AF board the HA1368R Audio Amp IC is available from time to time on Ebay and several TV Parts Supply houses. Also, If you cannot find a HA1368R DO NOT buy a HA1368 as the pin out is reversed. Search Ebay on this number 301077592721.

Most common subs that can still be found on Ebay and TV Parts Supply houses are the NTE1284 and the SK9268. DO NOT buy the NTE1283 or the SK9267 as again these have reverse pin out.

Lastly exercise caution during the unsolder/resolder as easy to lift a foil. Also, examine work under magnification to ensure no bridged pins.

Hey everyone
My wife and I are moving onto a sailboat so I have to sell my pride and joy station. It is for local pickup only so if you're within driving distance of Denver, you should consider it. The TS-830 is a true Gold, with all the filters in it PLUS the Metal KB-1 knob. I truly love this station and know I'll never be able to duplicate it but circumstances dictate I have to sell it. It's currently setup and in daily use, so when you come you can make some calls with it to check it out. Thanks, KD0RUR

Mike: I had a major problem with my 820S display.
If anyone tells you the through hole connections are at fault, they are probably correct.
It is easy to put a small piece of wire through the holes and solder.
I used silver coated jewelry wire from Hobby Lobby.
It solders like a dream (better than the wire on resistors etc)
Also you might look at all the traces with a good magnifying glass, I found one cut on my board. Looked like an exacto knife cut, You probably don't have this, but if the through hole soldering does not work, I would look.
Good Luck!

Hi Mike.
I had the same problem, and I have done everything that has been said by the network.
I cleaned the molex connectors, both of interconnection of the two internal PCBs and external, I soldier yarns between holes interconnect PCB of integrated circuits, I have re-soldered the molex connectors, and contunuaba having the problem.
The solution, for now, because I'm checking, has been reviewing all welds with a good magnifying glass and resolder I've seen something defective.
It is a task of patience, but it seems the final.
Best regards and good luck.

Hi Rafa, Terry and the other repairers of displays,

I understand why shotgun therapy is sometimes used but an analysis of actual causes would be useful when trouble-shooting.
Maybe Terry and others could rank and list their causes for us.

Mel,
I'm not totally sure what you are saying. What are you calling the "handbook," the operating manual or the service manual? I can not figure how you are comparing the drawing size to the physical size of the octal base as there is no relationship. It's for reference only...regarding connections/functions of the individual holes(pins).
I've been around the 820(S) series of rig for a good number of years and have never seen an octal base as you describe on the rear of an 820(S). I'm not saying that someone PRIOR to you did not change it.
  A quick check to see if it's the correct octal base with correct size holes for the pins, do this: using either one of your final amplifier tubes, remove it...and see if in can plug it into the octal base in question and fully seat. If it can...then it's the correct octal base, or use a spare 6146 series tube, that way you don't have to mess with the high voltage

TAKE PROPER PRECAUTIONS REGARDING HIGH VOLTAGE BEFORE REMOVING THE FINAL AMP COVER OR THE TUBE(S)....SIMPLY MAKE SURE THE IS NO VOLTAGE!!!! THERE CAN BE OVER 900VDC AT THE TOP OF THE PLATE CHOKE>>>> IT WILL KILL YOU!!! IF UNSURE, OR UNABLE TO TEST>> HAVE SOMEONE WHO KNOWS HELP YOU

I have replaced the drive tube but I am still not getting any drive indicator when I try to set using the manual. When I talk into the mic I can hear myself on my TS-480 but no RF indicator on the meter. I do have my VTVM with me now so I could use some help as to what I need to check next and how to test it. The VTVM is a HK 1M-18 and I don't know how to use it so I will need some help. Receive is GREAT on the radio.

Thanks
Carlos

Carlos,

Since you do not know how to use your Heathkit IM-18 VTVM, I highly recommend you spend time reading/studying the Heathkit IM-18 VTVM manual. You can download the complete manual from my website using the following link:

http://w5rkl.com/wp-content/uploads/2015/02/Heathkit-IM-18-full-Manual.pdf

Once the manual downloads to your computer, go to page 26, "Using your VTVM", to start learning how to use the IM-18.

Also, if you would please provide answers to the following questions:

1. Is the HEATER switch turned ON
2. What position is the rear panel SG switch set to? (normal operation position is "ON")
3. With the Mode switch set to USB or LSB, MIC gain set fully CCW, meter switch set to IP, press the microphone PTT button. What is the meter indication? (zero or 60ma?)

52717. Hybrid Net Update (Aug 2, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-08-02 21:47:05 UTC
From: Mark Gilger
Topic: 52717 Message: 52717

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday net was run by me, WB0IQK. There
were 22 stations checking in under poor good
conditions. We had the following number of radios checking in.

2 running TS-520(x)
1 running TS-530(x)
2 running TS-820(x)
8 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running a TS900

The rest were running non Kenwood hybrid equipment.

He was running my TS-830s + Drake L4B amplifier.

The Sunday net was run by me, WB0IQK. There were
17 stations checking in under poor good
conditions. We had the following number of radios checking in.

3 running TS-520(x)
2 running TS-530(x)
0 running TS-820(x)
8 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running a TS900

The rest were running non Kenwood hybrid equipment.

He was running my TS-830s + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo

Just completed my first business transaction with Walter Dilley KD7DNY who bought out Bob Manskers Kenwood Hybrid parts inventory.

Walter didnt miss a beat stepping in to Bobs shoes. He has barely gotten the parts unloaded and his feet on the ground and he took the time to locate the part that I needed and got it to me. His service was quick, price fair, and most of all the part was professionally packed to survive the rigors of the journey from Arizona to my home in Michigan.

We are lucky to have Walter to help us keep these treasures on the air. I wouldnt hesitate to buy from him and will certainly give him as much business as I can. I highly recommend you give him a try.

Ordinarily I wouldnt give a glowing endorsement based on just one transaction, but Walter met all the criteria that is important to me even before he had hung out his open for business sign. Should this turn out not to be his normal business practice I will be among the first to report that here.

Thanks Walter.

Mike,
I assume that prior to these problems that all was well?
You stated that you "rocked the band switch back and forth quite a bit."Did you see or feel any slop? The band switch should be tight and you should feel positive detents. It is quite possible that the band switch shaft coupler has cracked at one or more of the small set screws causing an "out of sync" condition between the band switch wafers on the RF board and S-22(in the final amp cage) that selects the taps for the various bands. You should inspect the coupler PRIOR to doing any more testing/tuning up. You'll need a real bright light..a penlight works well...to see if there are cracks, or any slop during "rocking" between the two shafts. UNPLUG RIG..LET IT SIT FOR A FEW MINUTES(10), REMOVE THE FINAL AMP CAGE COVER>>>TEST FOR VOLTAGE(DC) ON TOP OF THE PLATE CHOKE>>IF NO VOLTAGE remove the front final amp tube...you should now have a good view of the coupler. Rotate control over its entire range of movement...look around the small allen head set screws for cracks. I may be wrong...but check that coupler first, as it is a known fault. Possibly, to avoid future problems, several places to get a brass/metal replacement: hybridrestore"dot"com and k4eaa"dot"com

Thank you Joe for quick response to my latest problem...Yes I did check the coupler between front and rear
band switch shafts... All's well in that dept.. I have changed those couplers in the past so I was careful on that issue.Yes, the condition came on quickly... No warning....(no drive in half the bands),.Like I stated the bands where I do have drive it is meager. Less than FMD and not to top of ALC scale either...I used to have more than enough drive on all the bands...Strange that is just half the bands have NO drive at all...
Restate....some drive on 15m.20m.40m,80m..... NO drive on 17m,12m,30m,and 10m....I just had the VFO out and cleaned the varicap wiper...that's about it...Great radio...I do have it drivng a Dentron Clipperton amp. Now detached...Remote VFO also but,also, not hooked up....Any Ideas where I can start my troubleshooting???

Do you have an RF probe/VTVM or an O-scope?

In matter of minute should be able to isolate to where RF drive is low or missing. Are you familiar with the TX Level Diagram in the Service Manual? (need a 3 diode RF probe if going to measure RF drive at the Plate of the Driver tube, at Blue DRV lead wire, and at control grids of the 6146 finals)

Absent any test gear you can try another known good Driver tube and try pushing and rocking the tube in its socket (sometimes bad solder connections at the tube socket). A bad Driver tube plate choke usually effects 18 and 21 more so than lower bands.

Not often will lose the TIF signal from IF board, but it is possible.

Do you have approx 1.0 rms RF volts or greater VCO signal available at TP-3 on the RF board. This is the LO for the TX Mixer. Sometimes the black coax and/or its connectors from PLL board to RF board are bad. Have seen bad soldering at the coax sockets.

Typical RF drive voltages are:
1. TIF = 15rms or 45v P-P
2. TP-4 output of TX Mixer = 3rms or 8.5v P-P
3. DRV = 60rms or 170 P-P
4. Finals Cont Grids = 48rms or 136 P-P

Depending on the input capacitance of your measuring probes your readings can vary and you may have to repeak the Drive control as the probe can detune the Driver stage grid and plate tank circuits.

So point of all of this is just basically guessing unless your use RF voltage measuring test gear and run the TX level diagram.

Terry,

Thanks for responding. I didn't have a safety ground hooked to the back of the TS-530S, but I now have a 12-gauge wire hooked firmly to it, running to the outlet on the wall. I have tried plugging in the radio both ways, and I currently have it plugged in such that the S meter dropped about a quarter of an S versus the other polarity.

Otherwise my cables seemed just fine, but the high noise floor remains. Any other suggestions?

Thank you!

Hi Terry and thanks for your reply..... I do have VTVM and scope and Rf microvoltmeter(HP 411a)...Not sure if the last unit is in good working order....I'll have to look see if I have that documentation you mentioned to reference.You did get me right into the nitty gritty..... Please give me a little time to get the rig to bench to work on. Deal?I can try to rock the driver tube in the socket.. Quick check...I'll print out your steps to check and proceed tomorrow afternoon...Thanks for getting me started on the right path...Just awfully curious as to why HALF the bands have no drive at all... I just rocked the 12BY7 with send on and meter on ALC(In Tune)... No drive observed...
I'll let you know what I come up with ,Terry.......

Thanks , Mike (KD2DYY)

Cant just gently rock the tube. Have to press down firmly and rock at same time.

I thought you said you had no RF drive or essentially no RF drive on any band. If you have RF drive on low bands and not on higher bands then it wont be bad solder connections at the 12BY7A Driver tube socket. By RF drive I assume you are talking about ALC meter deflection in Tune mode at first loading step. A normal TS830 in good state of tune you should have full scale deflection in Tune mode with CAR level no greater than 1000 to 1100 (#3 to #4 position) with exception of 10 meters which will take more and may not be able to get FSD indication. Dont need FSD to load the radio, but should be able to produce it.

Couple of quick checks is to make sure you have at least 1 volt or more VCO signal level on all bands at TP-3. It looks like a resistor near the VCO cable socket. The 2nd test would be to see if you have approx 3 rf volts at the output of the TX Mixer at TP-4.

If you do have approx 3 rf volts at TP-4 on all bands then you know that you have good TIF signal from the IF board and good LO from the PLL and that the TX Mixer is working and you have RF drive at the control grid of the Driver tube. You are more than half way home.

Other thing you can do is measure the DC voltage levels at the Driver tube. DC voltages are not bandswitch dependent. Easier to do if you have a Pomona test socket, but if not it can be done carefully. Make sure you have good screen grid voltage, good anode voltage, and good operating bias on control grids of the 12BY7A tube. I prefer to measure RF signal voltages in and out and if low or missing then measure the dc voltages on the tube, but OK to measure the dc voltages if you cant measure the RF signal in and out.

It is possible that you have bad bandswitch contacts and the Driver stage is not seeing the tuned circuits, but kind of unusual to have so many bad contacts. If you have normal RF drive on the low bands and none or very low on the high bands then possible to have multiple bad bandswitch contacts or bad L36 plate choke, but as I say somewhat unusual.

You can also just go to the control grids (pin 5) of the Finals and measure the dc operating bias voltage and the RF drive on each band and work backwards from there. Assuming you have approx -65vdc you will need to have approx 47rf volts to see good ALC indication. 47 x 1.414 = 66.5 peak rf volts. Any RF voltage at the 6146 control grids much less than 46 volts and you will have no ALC indication. 46 x 1.414 = 65 peak rf volts. At 46 rf volts the control grids wont be positive with respect to the cathode and no ua grid current will flow and the ALC amp wont be biased on and the ALC bus voltage level wont be reduced and meter wont deflect up scale.

That about exhaust what I can provide to you.

Be careful taking any dc or RF voltages on bottom side of the chassis and Driver tube anode voltage can be no fun.

Mike

I forgot to mention if you want to measure operating bias on Final tubes with RF drive applied better to use a choke in series with your DMM probe tip if you want to measure directly on Pin 5. If you dont do that your meter may not like the RF and you can affect the RF drive and greatly reduce the RF output to the dummy load.

Better yet simply measure the negative dc potential on the long PC trace just after the FG terminal on the foil side of the Final board. That trace is the junction of the R1 and L1 so you wont have any RF involved at that junction. Actually simplest of all is you can just measure on the FG wire wrap terminal post.

Make sure you adjust the zero signal plate current to 60ma with the bias voltage adjust pot before taking this measurement. This adjustment will then present the dc offset that the RF drive must overcome on positive going peaks of the RF drive envelope to produce micro-amperes of grid current and ALC action.

Again if I understand what you are seeing and reporting what this will tell you is how much RF drive voltage you have on each band and assuming bias voltage is -65vdc then anything less than 65/1.414 = 45.97 or 46 rms rf volts will result in no ALC indication. You will have good full RF output just no ALC indication to use to peak the drive. Can use work arounds to peak the drive, but shouldnt have to do that. With approx 35 rms RF volts drive you will have approx 50 watts RF output.

I dont think I saw you report what the RF output is on each band?

MIke,

I have read info on how to use the VTVM. Very much like a DVM, need to make sure it is zeroed and that the AC DC switch is in the right position on the probe.

Power off, connect, power on.

Thanks
Carlos

I've reluctantly decided to part with my TS-520SE to make more room in the shack. It's in nearly pristine shape, having been formerly owned by a doctor who didn't have time to use it. I've checked into the hybrid net with it often over the past few months. The received and transmitted audio is awesome - for SSB, I prefer it to my other three vintage Kenwoods, but I'm primarily a cw guy. One problem is that I'd rather not ship it, so would prefer to sell it somewhere in the region so that it can be picked up or we could possibly meet half way. I'm located in Virginia, in the Shenandoah Valley, about 2 hours or so west of Washington, DC. I'm asking $200.00. Email me if you are interested and we can talk by phone for more information.

Name is Ron. Call is N2IIE. I just received a TS-830S about an hour ago. It's my first Hybrid. I've had a TS440SAT since 1988 as my only other rig. It still works fine. I was going to buy an Icom 7410 next month but saw the 830 on ebay for a great price (and a ham actually owned it).

I've always wanted an 830S so here I am. I got a dummy load and will have replacement tubes by the end of the week. I also ordered a K4EAA Band switch coupler. I already deoxed it and cleaned it up but plan to also replace the HV caps. What else?

I'm reading over as much info as possible and looked at all the tune up guides on ebay but I may be picking your brains from time to time. I'm happy to be part.of the group.

52735. Help: 530SP with horribly distorted, garbled LSB audio and what looks like ALC problem

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-08-05 01:59:30 UTC
From: marcwa1r@...
Topic: 52735 Message: 52735

I need some help with something. My 530SP has been working fine -- or so I thought -- from the time I first obtained it as a used rig about 3 years ago. The rig was freshly tubed then and it had been stabilized. The former owner, a doctor, sent his rig out for the work. A friend checked it out for me as my shack was in pieces due to a move and it turned out that it put out 127 watts on 80. At the time, stability seemed excellent, and so on.

Now, we come to the present. I have been noticing problems on LSB, especially on 80 where I handle HF net chores for my ARES and RACES groups. At first, the audio was strong but it seemed to fade over the last two or three months (I admit my hearing isn't as good as it once was), even if I stuck my ear right on the speaker. Also, it seemed there was no LSB output. My CW output was still in the vicinity of 120 watts or more, but when I checked the output on LSB on 80 I was lucky to be getting 28 or 30 watts, even into a dummy load.

Sunday morning I was listening to a weekly emergency net/roundtable. I figured that I would be able to hear them well as I put up a new, antenna Saturday that was hotter than a firecracker (at least the literature said so; I built it). But, no, I went right to the frequency where they were supposed to be and all I heard was the growl of a huge transformer in the front yard of our apartment (usually it is exceptionally clean, too) and I heard vague sounds of audio on LSB about on 3936. The frequency of the net is 3930. I tuned around to see if I could clean things up but the audio remained:

Low
Distorted
Garbled
Reedy

What can be ailing it?

The other or possibly same problem is that after tuning up the rig correctly. I always recheck the readings so and I found that after peaking the LOAD the reading on the S-meter fell to practically nothing, just a bit above the bump stop. Then, suddenly, the reading swept up to normal. Next, it started to jiggle around around, not remaining still.

Does anyone have any thoughts and what can I do to fix this?

73,

WA1R, Marc

Ron,

-Everything you□ve noted are good things to do with a new radio. There are more experienced hands on this board than me, but I□d offer a couple of additional thoughts:

-Sounds like you have, but download both the instruction and service manuals from the web. There are several places where you can get excellent scanned copies to use. Include these in your pre-reading, especially the transmitter tune-up instructions. Do it by the book! The 6146Bs are rugged tubes, but you don□t want to abuse them by staying □key down□ for too long during any particular adjustment. Take it in slow short steps when you start, allowing the tubes to cool between tweaks. Once you get the hang of it, you□ll get good at doing it quickly and efficiently.

-I presume you□ve given the radio a really good eyeball check, but you want to look for any hacks that might be present

-In your clean up, I also presume you□ve cleaned the band switch carefully. If not, this is necessary. Use a small artist type brush to dab contact cleaner on the contacts and work the switch many times; don□t just spray it. Be sure to do the ones in the final cage, too.

-Check the cathode resistors on the final amp board. There are four 20 ohm resistors in parallel from both cathodes to ground and they often have been stressed. You should see 5 ohms to ground measuring from either of the cathodes to ground. If it□s not close, suggest you replace them. They usually fail high and I have seen only one or two that have failed, but I always replace them all if needed. Use ½ watt resistors, as per the original design.

-SAFETY: Don□t mean to be preachy about this, but since this is your first hybrid rig you may already know that you have high voltages running around the tubes and power supplies, particularly in the final cage, RF board, etc., that can exceed 900V in spots. Be very careful when measuring or working around these voltages, I always ground the HV circuit at the top of the final plate choke before doing anything around the finals or HV supplies. I don□t count on the bleed resistors across the HV caps bleeding down the HV supply□I have often found that these resistors have failed (very) high, and that bleeds the caps more slowly than you may expect. Replace these resistors when you install the new HV caps.

-Be sure to neutralize the new final tubes once you install them. Check Ken K4EAA□s website for excellent guidance on this. CAREFUL here, too□use a non-conductive took to turn the neutralization cap, plus the final cage shields have to be on when you do this.

-On the band switch shaft coupler, carefully note the position of the two shafts before you take out the old coupler and restore this position correctly. If you get this out of sync, bad things will happen. I mark the shafts with a Sharpie to be sure. Once again, K4EAA□s site has good instruction on this.

Hope this helps. I have an 830S and love it□terrific radio.

I have a TS-820, VFO-820, MC-50, and SP-820 for sale, all in original boxes with manuals. It was purchased in 1978, with the all the original receipts and the logbook used which includes about a page and half of QSOs. Estimated time of use was about 2 -3 months in 1978.

The TS-820 includes the CW filter installed. The microphone, MC-50, looks like it was never used. Packaged in original box and plastic wrap.
The external VFO was installed and all the functions worked. It does not include the plug used in the TS-820 when the external VFO is not connected.

The rig has been tested and showed over 100 watts on all bands with a dummy load. However, a SWR/Power meter was used, which is not always accurate, so I can't give exact output figures. But everything appears to be working like new. CW contacts were made on 40, 20, and 15 meters with good reports. I don't have an antenna for 80 and 10 was dead.

De-Oxit (CorrosionX) was used on some of the controls that had dried out.

Pictures of the equipment are at the following link:
http://www.amateurradioreceivers.net/ts820.htm

The only blemish are two small spots on the right side of the TS-820, shown in the last picture in the link. We could not figure out what could have caused it except maybe being shipped around in the original box over the years.

The rig comes from a SK ham and some of the proceeds will be going to the estate. This was his only rig and was only active in the later 70's.

Price is $600 plus shipping. Contact me off list.

David White, WN5Y

I, too, have a 510 for sale.

I was a retread HAM after a looooong 26 year hiatus. I wanted to get back to the low bands.

Last year, I found the rig at a hamfest, got a dipole up and got back onto 40 CW . What with being a hard of hearing and veeeery rusty on CW, I found my return to not be quite the "kick" that I was expecting/hoping for. Then, I started having problems with the transmitter. The whole, popping of the 10 ohm cathode resistors that seems to be a common ailment with these rigs. (Personally, I think that operating 6146s with the 800V+ plate voltage is just asking for problems with very little return on investment, output power-wise. But that is just *my *opinion.)

I fought with that for awhile, replacing the resistors, repaired some very badly done repairs by a former owner, even located some nice new finals (not easy in this non-tube world we now live in) for it and got it back on the air for awhile. But after just a couple of weeks that familiar "POP!" and puff of smoke indicated that the resistors were gone again.

I was first licensed back in 1961 and this is *by far* the best rig I ever owned. The receiver is hotter than a $2 pistol, so even without a working transmitter, it is still a fine piece of equipment. But as I said, I'm just not getting the bump I was looking for so I'm just planning to pull the big switch for good.

I am willing to let it go for the best offer I can get. It's still connected to the dipole so you could give a listen it you'd like. I'm located in Pittsburgh, PA and would rather not get into the whole "shipping thing" but if you are somewhere reasonably close and would like this rig, let me know. We can probably work something out.

Topic: 52735 Message: 52740

Marc:

If I understand your problem, you are getting weak and garbled audio when receiving LSB signals on 80M, and you are getting low RF power output when transmitting LSB on 80M. A few questions: (1) I assume that USB reception and transmission (power output) are OK on other bands? (2) I also assume that LSB reception on 160M is wonky? (I suspect that if you have a 80M antenna, you would be able to receive (somewhat) stronger 160M signals at appropriate times of the day, propagation allowing.)

If my questions/assumptions are correct, then it sounds (to me) like you have a problem on all bands with LSB reception/transmission, but USB reception/transmission are OK on all bands.

I believe this points to a problem with the LSB BFO (IF carrier) oscillator (crystal controlled; 8.8285 mhz) outputting an incorrect frequency.

In the TS-530, the first IF crystal filter is centered at 8.300 mhz. In reception, the local oscillator at the incoming mixer operates at a higher frequency than the incoming signal, so that the incoming signal sideband is inverted at the IF frequency (a USB RF signal is converted to a LSB signal at the IF frequency; a LSB signal is converted to USB). So reception of USB (incoming signal) requires operation of a BFO (product detector) carrier oscillator that is slightly above the carrier frequency; the USB BFO frequency is 8.8315 mhz. Reception of LSB requires operation of a BFO carrier frequency that is slightly below the carrier frequency. The LSB BFO frequency in a properly working '530 is 8.8285 mhz. I suspect that this oscillator (which should produce a 8.8285 mhz signal) is "off frequency". This would result in demodulation of audio with a significantly "unflat" frequency response, since the demodulated signal is now not within the "flat" passband of the crystal filter(s). Transmission is the reverse process. This would explain the receive issues (distorted, weak audio) and the transmitter issues (weak power output, probably very distorted audio output also.)

Do you have a copy of the service manual, and the operator's manual? If not, get a copy; several of the group members post these documents on their websites (or check the yahoo group's file section).

To check the LSB carrier frequency, you will need either another receiver (capable of receiving CW at the BFO oscillator frequency) or a frequency counter. There might be other options to check this frequency; I will let other group members offer suggestions. (It might

be possible to check the BFO's frequency by measurement of the audio output frequency, but I haven't worked out in my head if this is really practical... This option might allow for use of a smart phone with an audio spectrum analyzer as the measurement tool...) You will want to be able to accurately set the LSB BFO's frequency (I suspect within plus/minus a hundred hertz or so), so if you choose to measure it with a receiver, it would require a receiver with accurate calibration.

I this sounds like a plausible explanation, and if my assumptions are correct, let us know. And advise what test equipment (receiver, and/or frequency counter) you might have available to proceed further. If the LSB BFO frequency is indeed "off" then it might be correctable by adjustment of the tuned circuit in the oscillator (which could shift the crystal oscillator's frequency by a slight amount), but if the crystal has let out its magic smoke then you might need a replacement crystal.

I apologize in advance if someone else has already answered your original email; sometimes my email server is flakey and delays emails by many hours.

Whoops, I need to make a correction: reception of a LSB signal requires operation of a BFO (product detector) carrier oscillator that is slightly below the center frequency of the crystal filter (not "slightly below the center frequency of the carrier frequency"). I have corrected the text below in the original email from Marc:

It is actually a 520S, but yes, I am interesting in sending it on it way.

What is your offer?

Mike,

Thanks for the detailed answer. You've hit the nail on the head with most of your analysis. You are correct that it is on LSB. USB and CW seem fine. The signals are strong. On LSB, it's just as I described it. The one thing that puzzles me is why I can't get a steady peak on the LOAD control. I have tuned Kenwoods for years. My first commercially made rig in 1980 was a then-new TS520SE. I love the rig and it did well by me. I made lots of QSOs as a General with it. That said, I have run across a hybrid Kenwood that I can't tune (or a Heathkit, for that matter). So, when I peak the LOAD I am confident that it will hold its value instead of dropping like a stone, coming back up to the right point on the meter and then jiggling around. I wonder if there might be two problems going on simultaneously? What would you think?

73,

Marc

PS a friend suggested cleaning the mode switch with some contact cleaner; it seemed okay when he said it, but the more I thought about it, the more I didn't think it was the correct move.

Marc,

You didn't say which band was involved, so I assume the loading issue is a general problem (multiple bands). I also assume that when you say the "S meter" reading falls to zero, you have the meter switch set on the "RF" position so you can peak the output using the LOAD and PLATE controls.

That said, I was having a similar problem a few days ago with a 530S I was working on. The output reading would drop to zero or swing to max when I was trying to load up the finals after dipping the plate with the PLATE control. What I found was that a set screw in the back of the LOAD air variable had come loose (cracked the paint holding it) and backed out some leaving the shaft to work back and forth and in and out. This was actually shorting the plates in the LOAD cap and unshorting them as I tried to turn the knob.

When I tightened this screw (taking care not to overtighten, as it controls the spacing of the cap plates), perfect operation was restored. I put a little nail polish on the screw to reset it.

I don't know if this is the separate problem in your rig, but you might want to take a look (take care of high voltage in the final cage!).

Marc:

If I understand your problem, you are getting weak and garbled audio when receiving LSB signals on 80M, and you are getting low RF power output when transmitting LSB on 80M. A few questions: (1) I assume that USB reception and transmission (power output) are OK on other bands? (2) I also assume that LSB reception on 160M is wonky? (I suspect that if you have a 80M antenna, you would be able to receive (somewhat) stronger 160M signals at appropriate times of the day, propagation allowing.)

If my questions/assumptions are correct, then it sounds (to me) like you have a problem on all bands with LSB reception/transmission, but USB reception/transmission are OK on all bands.

I believe this points to a problem with the LSB BFO (IF carrier) oscillator (crystal controlled; 8.8285 mhz) outputting an incorrect frequency.

In the TS-530, the first IF crystal filter is centered at 8.300 mhz. In reception, the local oscillator at the incoming mixer operates at a higher frequency than the incoming signal, so that the incoming signal sideband is inverted at the IF frequency (a USB RF signal is converted to a LSB signal at the IF frequency; a LSB signal is converted to USB). So reception of USB (incoming signal) requires operation of a BFO (product detector) carrier oscillator that is slightly above the carrier frequency; the USB BFO frequency is 8.8315 mhz. Reception of LSB requires operation of a BFO carrier frequency that is slightly below the carrier frequency. The LSB BFO frequency in a properly working '530 is 8.8285 mhz. I suspect that this oscillator (which should produce a 8.8285 mhz signal) is "off frequency". This would result in demodulation of audio with a significantly "unflat" frequency response, since the demodulated signal is now not within the "flat" passband of the crystal filter(s). Transmission is the reverse process. This would explain the receive issues (distorted, weak audio) and the transmitter issues (weak power output, probably very distorted audio output also.)

Do you have a copy of the service manual, and the operator's manual? If not, get a copy; several of the group members post these documents on their

websites (or check the yahoo group's file section).

To check the LSB carrier frequency, you will need either another receiver (capable of receiving CW at the BFO oscillator frequency) or a frequency counter. There might be other options to check this frequency; I will let other group members offer suggestions. (It might be possible to check the BFO's frequency by measurement of the audio output frequency, but I haven't worked out in my head if this is really practical... This option might allow for use of a smart phone with an audio spectrum analyzer as the measurement tool...) You will want to be able to accurately set the LSB BFO's frequency (I suspect within plus/minus a hundred hertz or so), so if you choose to measure it with a receiver, it would require a receiver with accurate calibration.

I this sounds like a plausible explanation, and if my assumptions are correct, let us know. And advise what test equipment (receiver, and/or frequency counter) you might have available to proceed further. If the LSB BFO frequency is indeed "off" then it might be correctable by adjustment of the tuned circuit in the oscillator (which could shift the crystal oscillator's frequency by a slight amount), but if the crystal has let out its magic smoke then you might need a replacement crystal.

I apologize in advance if someone else has already answered your original email; sometimes my email server is flakey and delays emails by many hours.

I need some help with something. My 530SP has been working fine -- or so I thought -- from the time I first obtained it as a used rig about 3 years ago. The rig was freshly tubed then and it had been stabilized. The former owner, a doctor, sent his rig out for the work. A friend checked it out for me as my shack was in pieces due to a move and it turned out that it put out 127 watts on 80. At the time, stability seemed excellent, and so on.

Now, we come to the present. I have been noticing problems on LSB, especially on 80 where I handle HF net chores for my ARES and RACES groups. At first, the audio was strong but it seemed to fade over the last two or three months (I admit my hearing isn't as good as it once was), even if I stuck my ear right on the speaker. Also, it seemed there was no LSB output. My CW output was still in the vicinity of 120 watts or more, but when I checked the output on LSB on 80 I was lucky to be getting 28 or 30 watts, even into a dummy load.

Sunday morning I was listening to a weekly emergency net/roundtable. I figured that I would be able to hear them well as I put up a new, antenna Saturday that was hotter than a firecracker (at least the literature said so; I built it). But, no, I went right to the frequency where they were supposed to be and all I heard was the growl of a huge transformer in the front yard of our apartment (usually it is exceptionally clean, too) and I

heard vague sounds of audio on LSB about on 3936. The frequency of the net is 3930. I tuned around to see if I could clean things up but the audio remained:

Low
Distorted
Garbled
Reedy

What can be ailing it?

The other or possibly same problem is that after tuning up the rig correctly. I always recheck the readings so and I found that after peaking the LOAD the reading on the S-meter fell to practically nothing, just a bit above the bump stop. Then, suddenly, the reading swept up to normal. Next, it started to jiggle around around, not remaining still.

Does anyone have any thoughts and what can I do to fix this?

Hi folks ,regarding the no drive complaint on my ts830.... I found the fault after getting the radio on the bench last night...I think I mislead myself and you folks, too, when I stated that several bands including 10m did not have any drive.Further scrutinizing the symptoms revealed I did, in fact, have drive on 10 meters..Going back to my original note, I stated that the last thing I did was to do maintenance on the VFO unit... Pull unit, clean the varicap wiper and reassemble to radio.. All fine and dandy...I did not think about what, ELSE, I did at that time... I noticed a broken wire in back of the VFO unit and assumed I must have broken it when I was working on the VFO...I dutifully spliced it back together thinking whew, saved that one...I have to add that I do not use the radio too often and it was several weeks since I did the maintenance on her that I tried to run her...That is when I noticed the issue!.... Symptoms being, no drive in JUST the WARC bands...(I think some of you are way ahead of my narrative at this point)...Thinking WARC only that was out.... I looked at the "Mod" these radios had to have to make them WARC capable..putting two and two together I scoped the wire that I spliced went to pin#1 of plug #6 (TOF) on the RF board...Well DUH..... That is the wire you CUT to able up WARC capability.......Cutting that wire abled up DRIVE to all bands again...Yes I AM embarrassed that I bothered you good folks with this...I did find intermittent connection at plug#7 (CAR) on the PLL unit and think that might have been the cause of my poor drive action on several bands... Lots of meter deflection is, now, possible on all the bands..I did use the radio last night on 17m and all seems well ....Again, sorry to bother you good folks...I have saved all your troubleshooting notes to a folder on my pc(Just in case) and I AM grateful for all your help....Specifically Joe(WB7UQU)Terry(K9TW) and Carlos(KE5DFK)..Thanks again.

Embarrassed, Mike (KD2DYY)

I would try adjusting TC-2 trimmer cap as a first step. The Carrier Osc trimmer caps are both accessible thru holes in the bottom cover. TC-2 and TC-3 trimmers are ceramic and often get stuck in one spot for long periods of time or will get dirty or will drift off position just from moving the radio around.

If you have a Frequency counter as was pointed out you can get on the CAR Molex connector on PLL board or on the IF board and watch the Car Osc frequency as you adjust the trimmer cap. For a starting point you can set it to 8828.500, but you arent done yet. If you cant adjust the oscillator frequency with TC-2 then perhaps TC-2 has failed or needs cleaned and exercised thru its range, the crystal has failed, or bad solder connection at the crystal pins.

Best way to perform the Carrier Osc set point or the SSB Frequency Response is to inject audio into the mic line and adjust TC-2 and TC-3 for 3dB roll off on the wattmeter. You do this by injecting 1500 hz and set the mic gain for 50 watts output. You use 50 watts as it takes some time to make the adjustments and dont want to stress the Finals at full IP key down. You then lower the audio gen frequency to around 350hz and adjust the trimmer cap for 25 watts on the wattmeter. Do this on both LSB and USB. Some like more bass response and some prefer more treble for a more communications style audio presence especially if they run barefoot.

The Service manual describes this method. You need a good stable and accurate audio generator. Best if you do Step 3 first and then do Step 24.

Other ways include injecting noise into the SO-239 and adjust the trimmer caps using audio spectrum analyzer software. Spectrogram works great. If dont have a noise generator then just find a quiet spot on the band where no QSO is ongoing. You can see Spectrogram traces under the Photos page on my website. I always use Audio injection into the mic line method and then document the as left using Spectrogram.

Can also use the Marker and Zero Beat method. Place AGC on Fast and the Marker on and then tune the VFO for zero beat. Adjust the TC-2 and TC-3 so that zero beat occurs at around S4 to S5. This takes a lite touch on the VFO knob. Zero beat is a slow rythmic motion or quiver of the S meter indicator accompanied by a rythmic "woosh" - "woosh" sound in the speaker. Not as good as the Audio injection into mic line method, but it does work.

Remember how you adjust TC-2 and TC-3 in Rx mode is how you will sound in Tx mode.

Marc:

In response to your statement that you are puzzled as to "why you can't get a steady peak on the LOAD control", here's my thinking: When you are transmitting (either LSB or USB), the audio signal from the microphone is bandwidth limited to (probably) around 300 to 3000 hz. If you are trying to generate LSB, and the carrier oscillator is working properly, and generating a 8828.5 khz signal, the resulting IF signal will consist of 2 sidebands- one of which is between 8825.5 and 8828.2 khz, and the other between 8828.8 khz and 8831.5 khz. The first one (8825.5 to 8828.2) is blocked by the crystal filter, and the second one (8828.8 to 8831.5) lies within the crystal filter's passband and is allowed to continue. The audio energy can be "somewhat" steady, and any RF that is generated has a somewhat "steady" level. But if the carrier oscillator is "off frequency", a significant portion of the generated IF winds up being poorly centered on the crystal filter's passband, so you get lousy audio (missing out on either the high audio frequencies, or the low ones, depending on whether the carrier frequency is high or low.) So the generated RF energy will tend to be more erratic.

Bottom line (my opinion) is that you need to look at the frequency of the carrier oscillator that is "supposed to be" generating the 8828.5 khz signal. There might be a description of how to check (and possibly adjust) this in the service manual.

Good luck and 73
Mike N4MWP

Dave,

It's worth a look. And, yup, I had the switch set to RF to enable the LOAD.

Mike,

You asked about my test equipment and I have to let you know that it is sadly lacking. I might be able to access some of this equipment at my club station over the weekend. At best, I may have a new (used) receiver in transit and arriving in about a week or so and until then I am stuck with either my club station option and nothing at all until the new (used) rig arrives.

73,

Marc, WA1R

Mike and all,

I agree 100 percent! The funny thing is hybrids are likely better than all of today's solid-state, surface-mount technology and computer-controlled rigs for a very basic reason, survivability. While today's rigs are much more capable technologically, they still can be whacked by EMP. The theory about where an aerial nuke should be placed to wipe out much of the nation's solid state infrastructure being somewhere over the middle of the country is still as valid today as when it was postulated 40 years ago. Where a hybrid with its "hollow state" finals, driver and discrete devices -- albeit with VLSI flat packs -- will survive an EMP blast quite nicely if disconnected and shut down, an all-solid-state device will likely be fried.

BTW, I will be working on my 530 when a newish rig arrives that I can use to beat against.

Wanting to do QRP with my 830 I look at the mod with 220K Ohm pot and 9V battery. I am confused as to where is would plug in on the back of the transceiver. We're talking 7pin vs 8 pin on the 520 and 820 ancillary socket. The 830 does not have an ancillary socket. Would someone please explain. thx

Cid,
Check TS-830S Instruction Manual, Page 13, Section 15 Remote Connector. QRP circuit can be connected to Pin 6 and ground. You could possibly use Pin 7(no connection) and connect wire to ground, or the DIN connector shell.

Cid,
I am interested to see if you have any luck with this mod. I built the circuit as shown and I am currently trying to make this work on my TS-520S but no luck, so far. I see you have discovered there is no "ancillary socket" and it is actually the remote socket. My user manual shows the pin out of the remote socket and lists Pin 6 as ALC feedback, so in theory this should work.
However, when I plug the circuit in, it appears to drive the ALC to nothing and I get zero output on transmit. When I put my volt meter on the circuit, the pot only drops the voltage about 0.2 volts, from 9.45v to 9.25v. My user manual states the ALC threshold is -6v, so that's not going to work.
I am also confused about the circuit as drawn. The text says to wire the pot in series with the (-) post of the battery and connect that to pin 6, which makes sense. However, the drawing appears shows the battery connected across the pot with the center tap going to pin 6 - ??.
I would like to hear from someone who actually built this mod and maybe see and picture of the wiring.

here's the post regarding use of the qrp circuit & car control:
A DIN Plug will be required to connect the simple DC circuit to theTS-830's rear panel REMOTE DIN socket pin 6 and ground. Tune up isnormal by following the instructions in the operator's manual. Oncetune up is complete, switch to sideband (USB or LSB) and adjust theQRP circuit pot for the desired RF output. The QRP circuit can bebuilt on a simple Radio Shack perf board and housed inside one ofthe plastic cabinets along with the 9 volt battery.

It's not possible to "preset" power output using the CAR controlwhen tuning the transmitter. The CAR control is used only in TUNEand CW modes, it's disabled in sideband. Adjust the MIC gain fornormal output then adjust the QRP circuit for the desired reductionin RF output level in USB or LSB. Do not use the QRP circuit in CWmode, use the CAR control to control power output level in CW mode.

When wired like this drawing y0ou described, you have a voltage divider circuit. Make sure the + side of the battery and pot goes to the radio ground (chassis) and the center pin of the pot to the pin for ALC on the aux/remote socket.with the QRP wires unhooked from the radio your battery should last for a long time/. The current thru a 100K pot will be about 0.09 Milliamps. My radio is Ham Radio...CW is Real Radio

Well, I built the circuit as drawn and I can confirm that it works on my TS-520S. I had neglected to attach the positive side of the battery to the pot and was running it straight to the ground, I only had a 200K pot on hand so that's what I used. In practice, all the "throttling" is done in the first 1/4 turn of the pot but it is still easy enough to dial in the desired output from 0-100W. I will post a couple pictures of the box with it hooked up to the remote socket of my rig.

The simple battery and pot QRP circuit is not required nor recommend in either CW modes. Power output in TUNE or either CW modes is controlled by a low DC voltage applied through the CAR control to the IF Unit's BM (Balanced Modulator) causing the BM to be "unbalanced". You can easily see this by studying the TS-830 high res schematic and following the CAR pot's "CV" wiper through the wiring harness to the IF Unit's plug 8 pin 1 and ultimately to the BM itself.

If you do not have the TS-830 high res schematic you can download it from the following link:

http://w5rkl.com/wp-content/uploads/2014/04/TS-830S-excellent-schematic.pdf

Hello everyone, My TS-530SP has a problem , I set the IP bias for 60ma , after a few cq,s the IP bias creeps up to over 120ma , it was suggested that the cathode resistors were under rated and change value , so I replaced these with 3 watt resistors only to find (I have been told) , they should be only half watt resistors because they act as fuses, however , even with new cathode resistors the IP still creeps up to over 120ma (at which time I do not tx in case of damage) Anyone know why this could be ?...73 Chris G4UDG.

Monitor the 6146 operating bias voltage and the screen grid voltage at the tube socket pins while this is happening and report back. Operating bias should stay pretty constant around -65vdc and screen grid voltage should remain pretty constant around 250vdc. If the SG voltage is slowly rising try cleaning the SG switch and exercising it a few times.

Chris,

I thought the belief that the final amplifier cathode resistors act as fuses was done and over with. Unfortunately it appears it's not.

Chris, the final amplifier cathode resistors do not act as fuses. Resistors make horrible fuses. First, read W8JI's findings on this idea

Cathode grid fuse resistors http://www.w8ji.com/cathode_fuse_resistors.htm

http://www.w8ji.com/cathode_fuse_resistors.htm

Cathode grid fuse resistors http://www.w8ji.com/cathode_fuse_resistors.htm Related page: Fault protection Please note the similarities in power amplifier protection and the Kenwood radio!

View on www.w8ji.com http://www.w8ji.com/cathode_fuse_resistors.htm
Preview by Yahoo

Now here's some math calculations that show the cathode resistors will not blow even with 350ma (FS IP meter) indication.

This 6146 cathode voltage with 350ma of IP current is approximately +1,.75VDC.

.35 x 5 = 1.75

The power dissipated in the cathode circuit is approximately .6125 watts. That's "612.5 milli-watts". Divide that by 4 and each 20 ohm 1/2 watt cathode resistor will dissipate approximately .153 watts or 153 milli-watts,''

Many, not all, cathode resistor failures are caused by arcing between the 6146 anode and beam forming element. The beam forming element is connected both internally and externally to the cathode. Therefore, when an arc between the anode and beam forming element occurs, the full anode DC voltage is present in the cathode.

The current in the cathode will be approximately 180 amps, not milli-amps.

900 / 5 = 180 amps

The total power dissipated in the cathode circuit will be approximately 162,000 watts.

P = I<srd> x R

180 x 5 = 162000

Each cathode resistor is subjected to the same +900VDC anode voltage so each cathode resistor will dissipate approximately, 40,500 watts

900 / 20 = 45 x 45 x 20 = 40,500 watts

You get the same answer by dividing 162000 by 4 which equals 40,500.

Age and long term abuse can also cause the resistors to fail. The resistors themselves make horrible fuses and do not react the same way as a fuse does.

Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday net was run by me, WB0IQK. There
were 28 stations checking in under poor good
conditions. We had the following number of radios checking in.

3 running TS-520(x)
0 running TS-530(x)
2 running TS-820(x)
8 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running a TS900

The rest were running non Kenwood hybrid equipment.

He was running my TS-830s + Drake L4B amplifier.

The Sunday net was run by me, WB0IQK. There were
17 stations checking in under poor good
conditions. We had the following number of radios checking in.

2 running TS-520(x)
2 running TS-530(x)
2 running TS-820(x)
4 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running a TS900

The rest were running non Kenwood hybrid equipment.

He was running my TS-830s + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo

The reason I didnt tell you to clean and exercise the bias voltage pot is because you set the zero signal plate current to 60ma and in doing that you would have had to at least minimally moved the pot and had some degree of wiping action. If you want to clean and exercise it and the screen grid switch that is fine.

The other possibility is a bad high resistant contact in LZN4 RL-1 aux control relay on IF board. You may think you are setting zero signal plate current to 60ma and actually setting it much higher due to IR drop across this relay contact which then supplies less voltage to the meter movement. It is also possible to have a bad contact in the meter selector switch but that is less common.

You can measure the voltage to the moving coil at the back of the meter and should see approx 0.072vdc with 60ma displayed in the IP position and approx 0.15vdc with 120ma displayed.

If you find the meter is accurately displaying actual plate current and operating dc bias and screen grid voltage are stable then I would try another pair of final tubes, however with operational hours you would expect the emission to fall off. I dont know what kind of final tube degradation would see plate current rise unless the tubes are very gassy and positive ion action at the control grids is negating the operating bias. Dont see this often with 6146 final tubes.

Terry,

I agree with using the AD5X 2 dB attenuator. I built it with relay control and it is installed in line with my rigs so as to be activated whenever my ALS-600 is turned on. Whenever the amp is off, the pad is bypassed by the relay. That way, I don't have to worry about turning the output down on the hybrid rigs-I tune to 100W and let the attenuator moderate input to the amplifier. All the equipment stays happy.

I have mentioned more than once how to build a very inexpensive attenuator pad to use to drive your linear amplifiers. For example search on Message 48942 or search on thick film resistor.

Hi Dave:

Using T-pad attenuators between the exciter and the linear amp are not new. Back in the day we built them, but didnt have these nice low cost thick film resistors that Phil Salas used for his attenuator. We had to find non-inductive high power resistors and they werent physically small. A nice simple homebrew project for someone who likes to build.

Take a look at Page 52 of this popular 1958 magazine. Author also does a good job of explaining why you dont use the Mic gain to control SSB power out. The BM carrier suppression is best if the correct ratio of audio input signal level to local oscillator level is maintained. We have discussed this on this forum as well as the practice of closing the plates of the Plate load capacitor. I should not pick that scab! Lets just say what you are doing is good practice.

Looking at the ads brings a smile to my face. Between my paper route money and my Dads help I completed Cleveland Institute and RCA Institute courses as a teenager. Very many schools back then and they all gave you good basic electronics fundamentals and then you could specialize in RF communications or TV Service or even Nuclear Instrumentation. Of course some cities actually had brick and mortar tech schools like DeVry and RETS where you could get a 2 -year tech degree. However, it wasnt all good as we could not Google on T-pad attenuators!

52780. TS-520 CW filter - possible to move center frequency down?

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-08-12 18:05:46 UTC
From: garrnich@...
Topic: 52780 Message: 52780

Hi Folks;

I have never liked the overall sound of the stock 500 Hz CW filter that came with my TS-520. The spectrum of ambient band noise presented seems rather high pitched and to me that is irritating to listen to.

I was wondering if the passband presented to the filter could be shifted a bit so the filter is letting through less highs and more lows (a "permanent IF shift" modification).

If possible, this change may upset the SSB quality, but I almost never use SSB.

I only have a DVM, but I do have a TS-430S. That's it for equipment. And the 430's IF shift gave me the idea to look into shifting the TS-520. When I use the TS-430S I usually set the IF shift somewhere between 10 and 11 o'clock to shift the band of white noise downward in frequency.

Looking into lowering the sidetone frequency would be secondary.

Does anyone know if the INRAD 400 Hz filter has a better overall sound than the stock Kenwood 500 Hz filter? The Kenwood filter seems sensitive to noise spikes and creates distortion without careful reduction of the RF gain. I am not speaking of selectivity issues here, but of the overall sound of the filters and their pleasantness/unpleasantness to listen to.

Comments?

Hi Garry.
Kenwood effectively filter 500 Hz causes a very high-pitched sound that is sometimes annoying. As I use a spectrum analyzer to center the signal CW, I have observed in my TS450S / AT, the bandwidth of the filter is 500 to 1000 Hz, but in my TS820S, I have to change the IF Shift down to the band width is also from 500 to 1000Hz. By doing this, I noticed that the sound is a bit more serious, not as sharp.
Not if you mean this in your comment. If so, try playing around with the IF Shift control.
Best regards.

Rafa and Garry,

None of the TS-520 series transceivers have an IF SHIFT control. The IF shift control didn't come along until the TS-820.

I don't know if you have considered this but if you are considering adjusting TC1 on the CAR Unit CW/TUNE crystal to change the 3395.4Khz crystal frequency, doing so not only changes RX CAR Unit BFO injection frequency to the GENERATOR Unit's Balanced Detector but also CW TX CAR Unit crystal frequency applied to the GENERATOR Unit's Balance Modulator will also be changed. I admit I have never adjusted TC1 so I can't tell you how much difference it will make but I do not recommend adjusting TC1 on the CAR Unit just to have a better CW receive tone. I recommend adjusting the RIT control for a better tone. The RIT is disabled in TX so any change made to the RIT control setting in RX won't affect the TX signal.

Thank you Rafa and Mike. However, my complaint is not with the tone of the CW signal itself. I know that I can move it around in the passband a bit by retuning with the RIT.

I wish to move the filter's 500 Hz window downward in the passband so that less highs are getting through and more lows are getting through. I'm thinking maybe 100-200 Hz. If it is still set to spec the CF now should be about 750 Hz with the upper limit for the beginning of rolloff at about 1000 Hz and the lower limit at about 500 Hz. I would like to move that entire show DOWN by 100-200 Hz to see if the overall audio spectrum sounds better.

I realize that I cannot change the frequency of the crystal filter, so to get this effect I would need to move the IF spectrum coming through it upwards in frequency.

Before getting out the owner and service manual and squinting at everything and scratching my head I figured I'd check to see if anyone has done this and how OR if it is an unfeasible idea.

The IF shift on my TS-430S accomplishes this objective by moving the SHIFT control counterclockwise from the centered position. I always set it to between 10 and 11 o'clock when I use that rig, because the entire audio passband sounds better to my ear that way. So I was thinking that maybe I could permanently adjust the old TS-520 to make a similar type of improvement. The TS-520 does not have an IF SHIFT. (Unless I succeed!)

Garry WA1GWH

52785. TS-520 front end mod

Yahoo group: TS-520_820_530_830 (2015 — 2016)

From: garrnich@...
Topic: 52785 Message: 52785

While I've got everyone's attention (I hope!), here is another TS-520 mod I've been wondering about.

There is a DK MOD that removes the first RF amp from control by the AGC and RF Gain control and allows it to run "wide open" (as the mod says). I am NOT looking for more sensitivity, which is the reason stated for this mod.

I have heard that depending on the design of an RF amp reducing the gain also reduces its IMD capability. So I am wondering if the front end (first RF amp) might have more robustness if it ran "wide open" all the time rather than being throttled by the AGC and by me as I reduce the RF Gain. (The AGC/RF Gain on the TS-520 also controls the IF gain, so it would still be functioning although somewhat differently.)

This rig was designed in the early 70s (parts of it maybe even earlier if copied from previous rigs) so it was not intended for current band conditions. I use it mainly on 40M CW with some 20M and 80M. IMD is very easy to hear on 80M especially on nights with high static levels and/or big signals around. 40M is not as bad, but the rig sounds so much better under quieter conditions on 40M or with front end attenuation.

SM5BSZ has described the receiver section of the TS-520 as "mediocre", but I'll be darned if I can find that link just now to post it.

I posted this question on QRZ a few minutes ago also.

I suddenly encountered this problem while using my remote VFO so I removed the remote and installed the jumper in the back to start my TS!

My crusty old service manual states the problem is no signal carrier coming in or no input is applied to the counter circuit.

Since this is a very mature radio in terms of service life I am wondering if someone has encounter this problem and what was the fix. The radio tunes fine so I believe this is just an indication issue.

Thoughts?

Frank,
Welcome to the world of the DG-1 malfunctions!
From your post, I assume the rx/tx function correctly? If so, then you most likely have the "usual" DG-1 problem. It was so prevalent, that Kenwood issued a service bulletin. The problem(s) are usually caused by intermittent connection(s) of the "through holes" or "vias" that go from one side of the COUNTER BOARD(x54-1160) to the other...there's...I think 18. Also, corrosion on the long pins that connect the COUNTER BOARD to the COUNTER MIXER(x54-1150-00) can also create a problem. The procedure is to clean all connection points with good contact cleaner and reconnect and disconnect several times and blow off with "canned air," aka "air duster." The more involved is getting some good quality small diameter wire...I use the ends off resistors..etc and a fine point soldering gun/pencil...40W or so works..and heat up one of the through holes and pass the wire...take your time..and identify the holes. It also helps to have very good magnification and a bright light while doing this...also inspect the pins around the IC's for cold/cracked or poor looking solder connections...and rework them...again with a lower watt soldering gun/pencil. This procedure usually solves the problem..if not...reinspect your work..it is possible however that an IC has failed.
I try and clean ALL connection associated with the DG-1 first,then test for operation, before I go and rework the counter board.
This is a problem that has plagued the 820S owner. Almost All Digital Electronics has a neat substitute for an other wise broken DG-1...but he is not producing any or taking orders due to some health issues.

Frank,
I doubt that the 5V AVR unit is to blame...as the unit/display kinda works.
As stated earlier, the COUNTER BOARD is the most likely suspect, and has given the 820S owners many fits over the years! If doing the "through hole" repair...spend some time looking at the COUNTER BOARD to identify the holes. There is one "through hole" that can only be serviced from the foil side...as it is under IC11. Also, as I stated earlier...good magnification and bright light really helps here. Good luck.
I'm going to be QRT for the rest of the day

Hi Frank

In "Photos" I uploaded the image plate integrated circuits in which the holes are to be resolder. They are 18 and one is low IC18. Also the other PCB I made a decision to land, welding wire and a small end one of the screws holding the box. In addition I have also reviewed all the IC plate welds, and all Molex connectors, and is solved.
Best regards.

Hello All,
My first, and only, rig is a TS-520. I'm looking to buy a second radio and was thinking of a solid state rig so I borrowed a Yaesu FT-450. The hybrid is so much better sounding that I'm stunned. The Yaesu sounds very digital and un-natural. Are there solid state rigs that sound as good as a hybrid? Pardon my ignorance but I'm new to ham radio and there is a hamfest next month. Your advice would be appreciated. Of course, I may just buy another hybrid - I'm in love.

Thanks,
Bill

I have a number of ‘tube radios’, (Drake’s and Kenwood’s) and yes, they do, generally, sound much better. With that said, I also have to say my Kenwood TS-2000X sounds pretty darn good, considering it is fully solid state. Also, keep in mind, the speaker you use makes a BIG difference.

I have a TS590S that I feel the same way about. Can I thread the needle on CW with it? Sure, but I still prefer the audio of my TS430S over it, especially for SWLing since it's general coverage and has the 6khz filter installed. It wins out over the digital rig. My TS530S also has the less fatiguing audio I prefer, so for casual operating on CW it's a toss up between the hybrid and the old solid state rig. So in my book, the older solid state gear might be worth investigating, just be aware of the issues that arise for that particular radio you might get interested in. Eham reviews and of course Yahoo Groups will be your friend in that regard.

Bill,

What sounds like a hybrid? A hybrid! I'm sure all the new golly-gee, super whizbang solid state with auto-tuner rigs are fine..as long as you can deal with all the small buttons, switches, sub-menues...etc...etc. Not to mention...if you have a failure..and rig requires servicing/fixing...doing it yourself...don't know about you...but all those IC's and SMD's are a bit much for me. As for the specific KW model...they all have their positives...and negatives...I have at lease one of each KW hybrid...but...overall...I tend towards the 830S...with all filters installed.Many 830S's have had at least the 455kc filter removed...and can bring a premium price if bought separately....of course..you can use an INRAD or FoxTango. Also, the KW hybrids tend to be a bit heavy for portable operation.

This topic will open a very lengthy "discussion"

Hello to Bill & all on this thread. I hope this finds you well,
Something to consider is that when talking about a Kenwood Hybrid of 520/30_820/30 series in receive we are essentially talking about a solid state radio. The receive section is solid state. The distinction here is that is analog audio vs digital. Also consider that Kenwood is also famous for their Hi-Fi audio gear and you begin to understand why they sound so good. If you are interested in an all solid state/digital radio there are quite a few options still under 1000.00 USD in the used market. Some have already been mentioned by others in this group. The Yaesu FT897/857 are pretty good as well as the Icom 706MKIIG. The IC-7000 is also very nice and these 4 radios lend themselves to portable and mobile ops as well. All can be had used from 650.00 USD.
If you are looking for primarily base ops an IC746PRO will give you HF thru 2mtrs with some dsp handles on the audio. If your pocketbook can stand it, a used IC 756PROIII is a great choice HF thru 6M. I have a proIII, A Drake B-line,a ts_830 w filters and an FT897d and side-by-each I can make them all sound pretty good but I like the Drake R4B audio the best. Actually, that's what it ultimately boils down to... only you can decide which audio you prefer. Any of the rigs in this email perform well and will do a station proud. See if you can find a way to hear your prospective rig(local club, field day, club picnic etc.) and see how they operate. Be patient and a true jewel will come your way.
Thanks for taking the time to read this ramble,Vy 73,
Mike_ K8SYN

I have a few all solid state rigs, Yaesu FT-757GX and an FT-857D. The receiver audio sounds okay but I must admit my Drake R4A and R4B receivers have great audio. My R4C receiver audio improved when I removed the original audio amp and installed the Sherwood solid state amp replacement but it's not as good as the R4A and R4B. The R4A and R4B have the same audio amp stage so they sound the same to me.

The Drake gear is great and fun to operate. There are the T4X/R4 combination plus the B and C Lines. The TR3 or TR4 series transceivers are also great fun. I had the TR3 and TR4C and they worked great.

Yes Drake uses sweep tubes but if you pay attention and don't abuse the finals add a fan on the rear of the final cage, the tubes will last a long long time! The final tubes in my B and C Line are old and they still produce full output. None of the Drake transmitters or transceivers, excluding the TR7, have cooling fans. I simply added a half wave rectifier off the filament line that powers a small 12VDC muffins fan. Keep the finals cool. Another thing, you can work on Drake gear, the TR7 may be a bit difficult without the extender boards, but the TR3/4, T4X/R4 plus the B and C lines are easy to work on. Manuals and schematics are easy to find on the web plus Gary, K4OAH has a great set of CDs that cover most of the Drake gear.

Have fun and enjoy what ever radio you decide to buy.

As someone else stated, a hybrid sounds like a hybrid. Like you, I have a TS-520 and love the receive audio. Unless you need a newer rig for no tune up, fast band switching, auto tuner, whatever feature, I would highly recommend picking up a TS-830. Warc bands, pass band tuning, notch filter, and that "Kenwood sound". I picked up a nice one several months back and am very impressed with the receiver. And that is comparing it to my Yaesu FTDX3000, which has a very pleasant to listen to receiver.

Stephen,
Do you have a good clear copy of the TS-830S Instruction Manual and Service Manual? If not, obtain one for free at either: w5rkl"dot"com or n6wk"dot"com Also, a large format schematic is available from k4eaa"dot"com very handy! You can have it printed out at a good office supply place to almost the size of a table top..it has voltages and test points marked......again VERY handy

What testing equipment do you have or, can obtain, and your level of knowledge? You may just need to do a basic alignment as outlined in theMaintenance and Alignment section of the 830S Instruction Manual.
If this rig is new to you, as stated earlier...get the Instruction Manual, review the location and proper setting(s) of all the switches and controls.
Sometimes, just proper cleaning of switches and other controls can, and has solved many problems, especially if the rig sat around for a long time without being used.
Also, remember to sign the end of your post(s) with...(at a minimum) your first name per group policy....tnx

Joe,
Sadly, the remote VFO-820 will not work correctly with the 830S.
  The frequency spread of the VFO in the 820(s) is 5.0 - 5.5MHz and the frequency spread of the 830S VFO is 5.5 - 6.0Mhz

Hi folks,

we had a few really hot days the last two weeks, 30-35 deg. Celsius nearly every day. I had two weeks vacation and spent it with my wife, my trusty TS-830S and an OCF dipole between two trees in a small hut near a lake in Brandenburg, NE Germany. During a long QSO the transceiver got fairly warm, not too hot to touch, but much warmer than usual. When tuning the upper frequencies in the 15m band (turning past ca. 21350 kHz upwards), I noticed that the displayed frequencies started to go lower instead of up! With the dial at 500 the digital display showed a unstable 21221 (the last two digits changing without touching the VFO).

I switched the marker generator on and had a very stable tone every 25kHz on the dial, regardless of the digital display. When coming down below 21350, the counter behaved normal.... I could reproduce this behavior at all bands, no useable digital display when turning the dial higher than about 350. Back at home, I can't reproduce it with a cold rig. Stable up to >500 at the dial...

Since I got a stable marker signal at every 25kHz all over the band, I suspect a heat problem at the counter board (or the VFO... I couldn't measure output voltage and signal quality of the VFO away from home). Any ideas where to look? I'm going to monitor the VFO input signal at the counter with a scope and heat the counter/VFO unit with a hair drier, trying to reproduce the phenomenon.

As Joe, WB7UQU said, the VFO-820 will not work with the TS-830. If you study the VFO-820 manual page 8 para 4.2, the VFO 820 out frequency range is 5.5Mhz at the bottom of ALL bands to 5Mhz at the top of all bands. TS-830 manual page 30 (Block Diagram) you will see the VFO output frequency range is 5.5Mhz on all bands to 6Mhz on all bands. There are a few KW remote VFOs that will work with the TS-830 and they are the VFO-230 and VFO-240. The VFO-120 has the same frequency range as the TS-830's internal VFO, I'm not sure whether the DIN plugs on the rear of the VFO-120 and the TS-830 will match up. I did a quick check of the VFO-120 rear socket and TS-830 Remote VFO socket schematic wiring and they both appear to be the same wiring but I can't say the sockets will match. Maybe someone else has a TS-830 and VFO-120 combination that's working who can verify this.

Martin,

You will need the TS-830 service manual available on my website

http://w5rkl.com/wp-content/uploads/2014/04/TS-830_Service_manual.pdf
http://w5rkl.com/wp-content/uploads/2014/04/TS-830_Service_manual.pdf

Check the DC voltages at alignment page 33 step 1.

To check the VFO output frequency range, connect a frequency counter to the REMOTE VFO DIN socket pin 1 (VFO signal) and pin 7 (ground).

Turn the 830's MARKER signal ON and set the VFO analog dial to zero (zero beat the MARKER signal). The frequency counter should display an approximate frequency of 5.5Mhz. Do the same at 500 on the analog dial and the frequency counter should be approximately 6Mhz.

To learn more about the PLL system, study the 830's Circuit Description section and PLL block diagram starting on page 4 in the service manual. This will help in solving your problem.

I Have most everything needed for repairs I have and still do run Swans and Drakes and service them myself but the Kenwoods are new to me. I have good copies of the manuals and services and copie ot the schematic, I was working threw the alignment procedure that's when I really noticed the marker problem there was no S meter response and very little volume and I was called for in many places in the alignment that it stopped me from proceeding I have stopped and looking to fix this before continuing thanks for any helpStephen kb7bgs
Do you have a good clear copy of the TS-830S Instruction Manual and Service Manual? If not, obtain one for free at either: w5rkl"dot"com or n6wk"dot"com Also, a large format schematic is available from k4eaa"dot"com very handy! You can have it printed out at a good office supply place to almost the size of a table top..it has voltages and test points marked......again VERY handy

What testing equipment do you have or, can obtain, and your level of knowledge? You may just need to do a basic alignment as outlined in theMaintenance and Alignment section of the 830S Instruction Manual.
If this rig is new to you, as stated earlier...get the Instruction Manual, review the location and proper setting(s) of all the switches and controls.
Sometimes, just proper cleaning of switches and other controls can, and has solved many problems, especially if the rig sat around for a long time without being used.
Also, remember to sign the end of your post(s) with...(at a minimum) your first name per group policy....tnx

52816. HYBRID NET UPDATE (August 16, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-08-16 21:00:57 UTC
From: Mark Gilger
Topic: 52816 Message: 52816

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday net was run by me, WB2KNR. There
were 9 stations checking in under poor good
conditions. We had the following number of radios checking in.

2 running TS-520(x)
2 running TS-530(x)
1 running TS-820(x)
0 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running a TS900

The rest were running non Kenwood hybrid equipment.

He was running my TS-520 + Heath SB-200 amplifier.

The Sunday net was run by me, WB0IQK. There were
7 stations checking in under poor good
conditions. We had the following number of radios checking in.

1 running TS-520(x)
2 running TS-530(x)
0 running TS-820(x)
1 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running a TS900

The rest were running non Kenwood hybrid equipment.

I was running my TS-830s + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total = 142, Sunday☐s total = 88
December 2014, Saturday☐s net total = 92, Sunday☐s total = 86
January 2015, Saturday☐s net total = 110, Sunday☐s total = 84
February 2015, Saturday☐s net total = 103, Sunday☐s total = 98
March 2015, Saturday☐s net total =80, Sunday☐s total = 51
April 2015, Saturday☐s net total = 59, Sunday☐s total = 29
May 2015, Saturday☐s net total = 79, Sunday☐s total = 48
June 2015, Saturday☐s net total = 70, Sunday☐s total = 38
July 2015, Saturday☐s net total = 26, Sunday☐s total = 56
August 2015, Saturday☐s net total = 57, Sunday☐s total = 42 (Month to date)

You say that off air receive signals seem normal on all bands. That is a good thing as it indicates L41 Ant Step-up Xfmr is not burned up.

Have you tried carefully pulling and cleaning Molex Conn 4 on the RF board and the PLL board? If not do that and report back.

Do you have an O-scope? If so you can measure the Marker signal at Conn 4 at each board. Helps if you have digital LP filter capability on the scope, but absent that capability can still measure the output and should see nothing less than approx 50mv P-P at output on PLL board and at input on RF board.

Dick,
Can't say if it's your cathode resistors or not...gotta measure them...a nominal 5 ohms to ground. As to why?...stuff happens...have you noticed in the recent past...increasing Ip reading when tuning up in regards to power output?
Since the usual thought is not to replace/fix it unless it goes bad...in this case..even IF your cathode R's are not toast...I would replace them with the SAME wattage and value as the carbon comp...just use metal film. It is possible that one or both of your finals may have had an internal fault...so again...recommend you obtain a pair of KNOWN GOOD finals to use AFTER you replace the possible bad cathode r's. Testing your final amp tubes in a "tubes tester" and getting a "good" reading or any other number that MAY indicate that it/they are good, will NOT guarantee that they will function in an actual RF operating environment.

Stephan,
Sorry for delay. I see that Terry-k9tw has given you something to check. I agree to check both connectors #4...one on the RF board...the other on the PLL unit. If you look at Pg 62(the fold out) of the Service Manual, you'll see that both deal with the "MKR" or marker signal from the PLL to the RF board. Be gentle with these connectors...they have been sitting for possibly 20+ years without being disturbed...and may crack the foil side solder pad/connection if made angry by too much pressure/prying. I usually give the connector a shot of cleaner/lube and let it sit for a few minutes before GENTLY pulling up (with good needle-nosed pliers) and a SLIGHT left to right rocking motion while holding the board side connector down with a tuning wand. The foil side of the PLL board is easier to view after removing a few screws...you can see the foil side of the RF board...but must remove screws...and GENTLY fold over the AF/AVR board to see the RF board foil side...better than removing the whole RF board
NEEDLESS TO SAY: DO THIS WITH RIG UNPLUGGED AND CHECKED FOR NO VOLTAGE.
 73 Joe wb7uqu

Thanks, Joe.

Here is some further info. I have no drive at all on 40M, which is what I was tuning when it died. Other bands seem to tune up OK.

I'm a Yaesu guy and although the 830S is not my main radio I am really attached to it and have been planning for a long time to send it in and get it tuned up and recapped. Maybe now is the time.

I also still have my very first radio, a TS-520S, which, like the Energizer bunny, is still going strong. Kenwood hybrids are hard to beat.

Michael,
Tuning up your rig into a dummy load and without an earth ground during testing/repair should not cause problems...it should not hurt your rigs innards, and should not skew any test results....my test/work bench is on the second floor, and I tune up through a watt meter and into a HEATH Cantenna that's located 6 feet away and have not had any problems. The operating position is on a different floor and is grounded...both RF and electrical.

Hi Michael!Earth Ground is a Zero (0) Voltage Reference Point. It has to do with electrical Health and Safety regulations. It has the least to do with our hobby since there is a huge difference between electrical ground and RF ground.On the other hand, Dummy Load shows a non conductive Impedance similar of the output of your radio thus allows you to tune it and maximize the output power as in ideal conditions.For static/antistatic reasons you need a good Earth Ground.To tune your radio you need a good Dummy Load of 50 Ohms!As simple as that and no harm to radio or monitoring equipment. 73Takis - SV3AUW / M0LPT sv3auw.blogspot.co.uk

On Tuesday, 18 August 2015, 6:35, "Joseph Stiles stilesjoseph@... [TS-520_820_530_830]" <TS-520_820_530_830@yahoogroups.com> wrote:

Michael,
Tuning up your rig into a dummy load and without an earth ground during testing/repair should not cause problems...it should not hurt your rigs innards, and should not skew any test results....my test/work bench is on the second floor, and I tune up through a watt meter and into a HEATH Cantenna that's located 6 feet away and have not had any problems. The operating position is on a different floor and is grounded...both RF and electrical.

The following link shows a copper ground buss bar that allows multiple devices to be attached then a single ground wire connected to an 8 foot ground rod driven into the ground outside the house.

http://www.dxengineering.com/parts/dxe-gbwm

I also recommend reading Tom Rauch, W8JI, website on grounding at the following link:

http://w8ji.com/ground_systems.htm

My shack is a separate building some 80 feet back from the house. I had the local electricians install power to the shack from the house through an underground cable. I had them drive a ground rod at the shack's electrical entrance and connect the ground rod to the shack's breaker box. This put both ground rods at the same ground potential. I simply followed Tom Rauch, W8JI, grounding website pages and have not experienced any grounding issues.

I have a problem with RF with my TS 520. I have several 520s and it only seems to be with this particular radio. When I use it with a tuner i noticed I would get rf burn on the tuner. I am now attempting to run it with an amp. 100 watts it seems ok, operate an amp and the 520 will burn you if you touch any metal including the decorative silver around the car adjustment.

Anything come to mind that would cause this in the 520? The rig is unmodified with the exception of the power cord.

Thanks Brian n nc kb4mng

Brian:

I sounds (to me) like your problem is related to inadequate RF grounding/bonding between equipment, and/or to adequate grounding/bonding of your antenna system. A lot of antenna systems don't have any problems with RF burns (or with "RF in the shack", manifested as TVI, or interference with other non-ham equipment) when the operation is at QRP levels, but as transmitter output power is increased, sometimes these problems start to rear their ugly head.

Inadequate RF grounding/bonding between your equipment can probably be corrected by providing solid RF bonding conductors (#12 or larger copper wire, or better still, copper braid) from the following:

1. If you are operating the TS-520 barefoot: from TS-520 to tuner.
2. If operating with an amp: from TS-520 to amp and from amp to tuner.
3. From tuner to RF ground.

The antenna system (antenna, feedline, tuner) is also (possibly) an issue. Are you using an end-fed antenna? End-fed antennas are notorious for being increasing difficult to feed without "stray RF" as power levels are increased. Describe to us what type of antenna, feedline, antenna grounding provisions, antenna tuner, etc you are using. Also if any baluns or ununs are part of the system.

Also, don't forget to provide a solid AC power bonding jumper (from your AC power system's grounding conductor) to the TS-520 and the amp. This is for safety purposes, although it might also help with your stray RF problem.

I haven't seen the most typical comment on this sort of problem: band switch cleaning. If it has already been suggested, I apologize. On some of my 830's, I have an intermittent issue with drive on 40m - it is the band switch. Maybe it is the position of the 40m tabs, but the 40m operation does seem to be the one most affected by the dirty band switch. Until I figured it out, I also thought the rig was possessed.

Just had a couple of question. If I connect an rca plug to the ancillary socket on the 520, the two pins that would be utilized is pin 1 and 5, is this correct? The center could go to pin 1 and the outter to pin 5. When the TS 520 keys, these two are connected, is that correct? This connection on the ancillary socket will allow 12v to reach a 12 volt relay to cause activation. Would this harm the 520?

Thanks, Al. All seems to be well now. Based on your experience I wiggled the band switch and got no reaction from the radio. Based on my experience this is a temporary reprieve as problems NEVER disappear of their own accord. The radio is overdue to go in for a super-tune so maybe now is a good time.

Greetings I hope this post might help as I just restored my TS-830S

Problem was I had no side tone and it would not key my cw with vox on !

After reading alot of post on the internet, it came down to just check your voltage on the RECTIFIER UNIT at "STB" you should have around 113 Volts. If it is missing just pull R12 1/4 watt and R13 1/2 watt and check to make sure that they are at 100K Ohm.. R13 on my unit was open ! Replaced and I'm back in business. I hope this will help and save you time !

Topic: 52838 Message: 52838

After finishing the install of the flash and glitch protection on the 830's that I have, I decided to try the TS820. The RF board is different, so component placement has to be adjusted, but the compartment with the HV caps is very small and I don't see any way to attach a solder strip for the glitch resistors without drilling a hole or making a special mounting bracket to use with the resistor board anchorage just outside the compartment.

Has anyone tried to add the glitch resistors to the 820 HV compartment? If so, how did you mount the solder strip?

Thanks,

Bob/W6JZR

Oh yes, I already did that. The 820 RF board is a little different, so the component placement had to change from the 830, but my question is how to fit the glitch resistors down into the tight area of the 820 where the HV caps are.

The 830 was easy.

Topic: 52835 Message: 52841

Brian,

You have the pin connections to the RCA plug "backwards'.

The "center" connection of the RCA plug connects to the TS-520 "REMOTE" 8 pin socket, pin "5" not pin "1"!
The "outer" connection of the RCA plug connects to the TS-520 "REMOTE" 8 pin socket, pin "1" not pin "5"!

Yes, when the TS-520 changes to transmit, the TS-520 relay "energizes" causing pins 1 and 5 to short together allowing the amplifier's RELAY to "energize".

Pins 1 and 5 on the TS-520 8 pin octal REMOTE socket act as a mechanical switch to control the amplifier's relay. In receive (standby), the relay is not energized result in the terminals to be "Open" but in transmit, the relay energizes causing the relay terminals to short together like a switch. The opposite occurs when switching back to receive.

You can use simple stereo interconnecting cables found in DVR and/or old VCR boxes or youc can buy ready made RCA cables on Walmart but their expensive. You can also make your own cables using RG-174 coax and an RCA plug and an 8 pin octal plug. You can find the 8 pin octal plug on eBay..

Topic: 52835 Message: 52843

Brian,

I forgot to mention.

If you connect the amp's relay cable as you described, the amp relay will energize without the 520 being keyed and when the amp's turned ON and the amps STBY/OPR switch is set to OPR. How does this happen? If you look at the 520 relay pins, 5 is a "N.O." (Normally Open) relay terminal and pin 1 is "ground". If you connect the amp's RCA socket "center" conductor to pin 1 on the 520, by simply connecting the short length of coax between the 520 and the amp will, when the amp's STBY/OPR switch is set to OPR, energize the amp's relay! The coax shield completes the relay circuit.

The amp's relay RCA socket center conductor MUST be connected to the 520's Remote socket pin 5 NOT pin 1.

Just go one board after the other. I recapped several old rigs (mostly HiFi gear from the 70s) like this. It pays to take (mental) notes of the orientation of each and every cap you're removing, there are errors in the documentation and/or the silk screen print on the boards. The Kenwood boards of this era are somewhat touchy to work, the traces lift of easily. When in doubt, check the continuity of the traces with a beeper after soldering the new cap in.

I use a cheap chinese desoldering pump, but with single side boards you can get by with a soldering iron and solder wick. Just heat one pin of the cap while pushing the cap the opposite way and repeat this with the other pin. Usually only one or two tries will get the cap out and you can clean the pad with the wick. Of course, this works with radial caps only, but most are radial types. After recapping one board, I check the solder pads of all molex pins with a magnifier and resolder all odd looking ones.

When recapping my TS-830, the only problem I had was a broken wire, fortunately easy found. The movement of the boards are stressing the wires, don't overdo it.

Hi Bill,

Ask yourself why you're doing it because if there
are specific problems you a trying to resolve
you'd be better off spending some time
understanding what parts of the circuit are involved and targeting those first.

There's plenty of stories in this group of those
that have recapped their radios and ended up in a
mess. In my opinion recapping just because
something is old isn't a strong enough reason but
I get that some folks think it's necessary.

If you do want to go ahead with the recap give
your radio a thorough checkup before you start
and make note of anything that might be wrong now
and what is definitely working. Nothing worse
than finishing a job then wondering if that
problem was there before you started.

Do one section at a time and check your work as
you go. If something goes wrong it will be much
easier to resolve the issue if you know roughly
which area you were working in before the fault happened.

Good luck

Lou

As others have stated, I would not do a recap unless necessary. Power it up and use it awhile. I use to own a 830 and currently own a 530 and 5 520s. None of them needs a recap. I did replace the filter caps in the 530. the only reason i did that was because I had the rig apart and did it as a precaution.
I have never personally known or heard anyone that had to recap a hybrid. I'm sure they are out there but I have never heard.
If you proceed with the recap. I suggest take a lot of pictures. I have found what seem simple and common sense when I start removing parts is'nt when time lapses and I start questioning myself. Do a board at a time and then use the rig awhile.
Not sure about your radio. But I know the 520 boards are nicely wire wrapped and would hate to start removing the boards for a recap.

Bill,

You ask for some "insight" or "heads up" about what you are about to do. What you are about to do is referred to as "Shot gun capacitor replacement" and it is NOT recommended and is "unwise"!!

If your TS-820 does not have any problems now and you perform the "shot gun capacitor replacement" of all caps in the TS-820, the chances are rather high that you will create problems the TS-820 did not initially have. For one thing, the foil runs, component and plug pads are very sensitive to heat. Repetitive heating of the pad and foil runs can easily create cracks in the copper foil pads and runs that causing a circuit or circuits to fail. Another thing is removing the board requires removing the wiring harness wire wrap connection. When installing and reconnecting the wiring harness to the board(s), its rather easy to make connection errors that can easily damage components on the board which leads to other problems. Poor soldering that creates shorts between foil runs and/or pads creates more problems. Installing electrolytic capacitors "backwards" can easily cause problems.

If troubleshooting a problem finds a bad component (resistor, transistor, FET, vacuum tube, or electrolytic capacitor) that's the source of or contributing to a problem, replacing that component(s) is one thing but to "shot gun" replace every capacitor in the radio simply because the capacitors are old is pure non-sense and is NOT recommended!

Having said that, it's your TS-820 and you can do what every you please with it.

I would replace the 900vdc and 300/210vdc supply filter caps and not replace any others unless troubleshooting reveals that an electrolytic cap is the root cause of the operational issue. I recommend replacing the 4 above caps as they are in high energy service and when they fail can cause collateral damage. Almost always they will ESR high and the rupture vents will be swollen and cracked (easy to inspect visually). I recommend replacing these under the preventive maintenance/life extension umbrella.

KW repair techs who promote,sell, and perform wholesale replacement almost never tell the customer that in addition to new filter caps they are getting back a radio that has defects on the PC boards that it didnt have when it came to their shop. Defects include dragging solder across cracked traces to bridge the break that they induced and jumper wires to replace lifted pads and foils that were not there. The owner is none the wiser.

Also, very common to reverse polarity a cap due to lack of attention to detail and relying on schematic and/or silk screening that is in correct. Almost always the as built factory installed config is correct. Places include negative dc supplies like -C and -6vdc, AGC detector diode back bias, PLL board, Counter Mixer board etc. These circuits require that the positive lead wire of the electrolytic be soldered to the PC board ground plane.

It would seem intuitive that it would be a good thing to replace all the electrolytic capacitors that are 35 to 40 years old. Just make sure you understand the risk vs the reward. Most of the time the reported performance improvement is self-fulfilling and not measurable.

Same with replacing all the carbon composition resistors. Never hear anyone promote that. Wonder why? It is very common for them to drift high or go open. In your TS-820 almost a certainty that R13 and R14 Driver tube screen grid divider resistors will be high and the 82K may be open.

Just saw a post about the STB divider resistors on the TS830 going high. That is not only a STB problem it is a safety problem as you loose the 210 supply bleeder. R9 330K on the TS830 rectifier board very often is open. This results in a rattlesnake waiting for you as the 300 supply caps will stay charged for days after rig is down powered and unplugged from the 120 recept and you may find it the hard way barehand poking around the HV rectifier board and/or the Final board.

See Message 47192 and several others regards wholesale electrolytic capacitor replacement.

Not saying it cant be done. Just need to realize what trouble you can induce if you are not knowledgeable, experienced, and have the right soldering and de-soldering tools to work on these old phenolic boards.

So I made the little box for The 830 so I could run 50W into my AL-811. The QRP unit works very well. Then I realized that by using the DIN plug in the ACSY connector I no longer had a send switch. (silly me). So now I must add another thin shielded cable and solder two more wires on the DIN PLUG for the 'send' control. I did post couple pics and then saw someone else had done the same before me. I love Ham Radio. 73

Hi Terry. Interesting posts and of great value - especially about the STB divider resistors on the 830. Not wishing to sound naive but what does STB stand for please?

Best regards, David G4TUP.

First I had this radio since the early 90's it worked great. The display would get a little wonky but then clear up.
I set it aside to take care of lifes other issues. I had it fired up about 5 years ago but it started getting erratic so I set it aside again until I could decide what to do. Finally it just died all together. I just replaced the HV caps and a few others that were bulging and way out of spec so now it powers up but Im going to leave it at that for now. Im tired and thats no time to fool with a radio. The display still dosen't light up but I'll take a fresh look later after I had some rest. Thanks for all the reply s and concerns It means alot to have good people looking out.
Bill

Best tip I had was to use a sharpie to colour in the top of all the existing caps so you can see at a glance where you're up to.

That way if you take a break, answer the phone whatever you'll know exactly where you're up to.

Other than that take you time-I found it quite therapeutic...

David,
"STB" is the side tone voltage. It goes from the STB post on the rectifier unit to the STB post on the AF unit. If you look in the 830S Service Manual Pg 62...(it folds out) you can see a list by board/unit of the connectors, terminal numbers, their marking, what its use is, where it goes...and to what connector and pin number....very handy.

David:

A phase shift oscillator is used to generate the sidetone. Feedback from the collector to the base of Q1 on the Audio Board thru phase shift RC networks is controlled by diode switch D1 in series. That diode is biased by STB and Key. Some refer to STB as Side Tone Block and others refer to it as Side Tone Bias. I am in the Side Tone Bias camp. STB applies positive dc voltage at all times to D1 diode anode. Key applies block bias of approx -66vdc to buck the STB voltage when the code key is not closed. When the code key is closed Key goes to zero and D1 is then forward biased and turned on completing the oscillator feedback path to produce approx 750hz tone.

David

You didnt ask but you also need STE for the phase shift oscillator to function. It grounds the Emitter of Q1 when the mode switch is in Tune and CW position. Some refer to it as Side Tone Emitter and others as Side Tone Enable. I like the latter.

STE also is used to change the receiver CW audio frequency response of the audio pre-amp stage by grounding the diode "tone switching" path. This places a pi configured rc low pass filter in the path.

David

I am sorry but it has been awhile since I had a problem with the TS830 side tone oscillator circuit. I also forgot to mention STS which I like to refer to it as Side Tone Silence. However, the 830 Service Manual describes it as Side Tone SW or Switch under the Remarks column. It is a ground that is derived from the Key jack. Without a key in the jack STS places a ground across Q1 base bias divider resistors R8/R9 and Q1 is turned off. With a code key inserted in the jack the bias is restored to Q1. So the oscillator is now turned on if mode switch is in CW but no Tone yet as D1 switch is still open in the RC phase shift feedback network until code key is depressed and Key voltage removed that is bucking STB and keeping D1 reverse biased.

So three things involved in getting the oscillator turned on. 1. Forward bias D1 to complete the oscillator feedback path 2. Ground Q1 emitter 3. Apply bias to the base of Q1.

STB = Side Tone Bias
STE = Side Tone Enable
STS = Side Tone Silence or Switch

I dont know of any place you can find a single complete list of the KW schematic abbreviations. Some are pretty intuitive and others a bit cryptic.

David,
TNX fer ur nice comment...I stumble along...and get things right once in awhile...hihi..Terry-k9tw, Mike-w5rkl...are both more knowledgeable than me regarding electronic theory/repair
The topic of re-capping is a subject that keeps coming up. As you found out...there is no significant reason to just re-cap...EXCEPT for the aged HV caps and the filter caps for the final amp & driver screen voltage supply. Failure of one(most common), or both of the HV filter caps can, and will damage other parts of the rig, making repair very costly..if ya gotta send it out...or very frustrating if you are tracking down many...many faults because of HV cap failure. The HV(etc) are rather cheap....considering the alternative

Yeah, I replaced my HV caps but te display ids still out I noticed after warming up a bit and moving the band switsh there was a little smoke from something getting warm on the coil pack board, the one with the driver so I shut idt down to investigats. I did hear a pop but it doesn't look like a cap blew and the sound came from the other side of the radio. I at first thought it was my computer monitor...We'll just take our time and look at it .

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday net was run by Jimmy, WB2KNR. There
were 5 stations checking in under poor
conditions. We had the following number of radios checking in.

2 running TS-520(x)
1 running TS-530(x)
1 running TS-820(x)
0 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS900

The rest were running non Kenwood hybrid equipment.

He was running my TS-520 + Heath SB-200 amplifier.

The Sunday net was run by me, WB0IQK. There were
13 stations checking in under poor
conditions. We had the following number of radios checking in.

1 running TS-520(x)
2 running TS-530(x)
1 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS900

The rest were running non Kenwood hybrid equipment.

I was running my Drake TR-7 + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total = 142, Sunday☐s total = 88
December 2014, Saturday☐s net total = 92, Sunday☐s total = 86
January 2015, Saturday☐s net total = 110, Sunday☐s total = 84

Bill,
If you are looking for a LARGE format schematic for the 830 or the 820(s) you can down load one from: k4eaa"dot"com home page. look for "large format schematics" I have one on the computer and put the file on a thumb drive and took it to a Kinko's and had them print it out...it's about 18" by 36" has voltages marked and it's easy to read

Bill,

If you are looking for high resolution schematics for the TS-520 and
TS-830, I have them on my website for free downloading. Simply click on
the following links for each schematic:

TS-520S
http://w5rkl.com/wp-content/uploads/2014/04/TS-520S_LARGE-Schematic_Hi-Res.pdf

TS-830S
http://w5rkl.com/wp-content/uploads/2014/04/TS-830S-excellent-schematic.pdf

52869. Kenwood R599A - No Receive

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-08-24 03:51:02 UTC
From: kawninja@...
Topic: 52869 Message: 52869

Hi all,

First time poster here. Been wanting a cheap hybrid HF rig for some time and picked up a set of Kenwood 599 twins at the local hamfest this weekend. Apparently came from a SK that passed in 2003 and been in storage since. Got them for $50 with matching speaker.

Trying to get the R599 going first. I think it has two separate problems... bad or very dirty AF Gain pot and no receive.

Regarding the AF Pot... you only hear audio "pops" when you freely turn it... but turn it very carefully within these "pop" areas and audio does work. The marker signal comes in loud and clear. Also getting low level white noise when marker is turned off. You can tell all modes work, RF Gain works, band switching works, etc.

Regarding no receive... it's almost like the antenna input is somehow disconnected. I do get low level white noise when the AF pot wants to cooperate and the internal marker works great. It reminds me of a receiver having no antenna connected... when it actually is.

Any ideas are greatly appreciated. Thank you!

Steve

Topic: 52869 Message: 52870

Steve,

First, you did not specify whether you have the operator and service manuals for the receiver and transmitter. Second, you can't do any troubleshooting with your T599/R599 transmitter and receiver without the schematic and service manuals.

The following links will allow you to download, free, the service manuals for the transmitter and receiver and the operator manuals for the transmitter and receiver.

T599 and R599 Service manuals:
http://w5rkl.com/wp-content/uploads/2014/04/R599S-Service-Manual.pdf
http://w5rkl.com/wp-content/uploads/2014/04/T599S-Service-Manual.pdf

Schematic
http://w5rkl.com/wp-content/uploads/2015/02/Kenwood-R-599D-Schematic-1.pdf

R599 User manual:
http://w5rkl.com/wp-content/uploads/2014/04/R-599-Operating-Manual.pdf

T599 User manual:
http://w5rkl.com/wp-content/uploads/2014/04/T-599-Operating-Manual.pdf

What position do you have the "AUX Bandswitch" (switch to the right of the band switch) set to? Make sure the AUX Bandswitch is set to "HF" not 50A, 50B, 144A or 144B.

The reason the MARKER (Calibrator) signal is strong is because the MARKER output is connected directly to the receiver's RF Unit board and does not go through any band or mode switches. You can see this by studying the schematic (available at the link below).

I also recommend you clean the pots with DeoXit F5 Fader cleaner/lub. Give a small amount of cleaner into the pot and rotate the pot throughout it's rotation range a number of time. Following the cleaning process with generous amounts of canned air, found at Walmart TV/DVD/Cell Phone department or compressed air to remove any/all cleaner residue while rotating the pot throughout it's rotating range. This should eliminate the scratchiness of all pots.

Clean all band, Mode, and Function switch wafers with DeoXit D5. Apply a small amount of cleaner on each wafer switch contacts, rotate the switch throughout it's range several times, and follow the cleaning process with generous amounts of canned air/compressed air to remove any/all cleaner residue from the switch wafers and surrounding boards/components.

You can find and purchase DeoXit D5 and F5 cleaner and lub on eBay and other online outlets. Use only enough to properly clean the switches and pots. Do NOT spray a lot of cleaner.

Make sure you have the interconnecting cable connected between the receiver and transmitter. That's the one with the 13 pins on each end. If you don't have that cable, then you'll need to jumper several pins on the receiver's remote connector in order for the receiver to receive anything. See the operating manual.

Ron,

Depending on what email client software you are using, you most likely can configure a message signature that will be automatically applied to the end of any message you create or responses you make to other member messages.

I use Thunderbird and have the ACCOUNT OPTION configured to apply a message signature automatically to the end of every message I create or respond/reply to. That way I never have to worry about adding the signature.

Not to be disrespectful but this would make it easy for those members who don't pay attention or forget to add a message signature to their messages/responses before they send their message(s). That way you will always have a signature at the end of every message you send to the group.

Thanks for the comments! Had no idea the R599 required the interconnecting cable to receive. I though it would work just "stand alone"... so that clearly explains why it has no receive. Fortunately I do have the cable.

So does the T599 actually need to be powered up for the R599 to receive? My T599 is a bit "questionable" at the moment. It didn't make it through storage as well as the R599. Definitely not horrible... but needs a bit more attention than the R599 before applying power. I'm not that far just yet.

I don't see in the manuals how the R599 can be jumpered without the cable to receive. Can you point me in the right direction?

Appreciate all of the help. Thanks!

Let's clear up something first. Your subject header says R599A and your text says R599. Which one do you have (they're two different models)?

In the R599A manual, I believe it's Figure 8 on page 18 that shows you the jumpers in the remote connector plug that was shipped with the R599(whatever) out of the box. You can also see the jumper connections on the schematic (lower left I believe). The T599(whatever) doesn't have to be powered on when you connect the remote cable from receiver to transmitter for the receiver to work (if everything else in the receiver is functioning). I would suggest reading the operating manual(s) for both units to get a feel for typical operation and functionality before really diddling with them. The Twins are a great combo; I'm the original owner of my 599D Twins and still use them frequently. The transmitter also sounds great in the AM mode.

In the R599 operating manual, the remote connector jumpers are shown on page 4, Figure 2. I think in my earlier post I also said it was a 13 pin connector; it's really a 16 pin connector.

Hi members,

I do have both the JR599 and the R599D and the associated transmitters also,all in prestine condition.

Time to time in past I do have operate the JR599 and R599D without the interconnection cables connected to the transmitters and I do have receiving signals

About internal speaker,I can not remember those equipment has a internal audio speaker,they originally have not for sure !!

If so modifications has been done on it …

I am not talking about some jumpers on external connection plugs they are …

Like Pete told they are great equipment to obtain,and they operate outstanding despite they have no WARC bands on it …

Regards Jean ON4AEF.

The jumpers are the same in the R599 receiver remote plug regardless of the receiver model. The jumpers are shown in the R599 operator and service manuals.

The R599 is not required to be connected through the interconnecting cable to the T599 transmitter if all you want to do is listen using the receiver.

For simple receiving where the R599 is NOT used with any transmitter, the only jumper required is between pins 2 and 11, the other jumper (4 to 5) and wiring to pins 7 and 16 are NOT required. You can see this by studying the R599 schematic.

Pins 4 and 5 are connected together to provide B+ to the R599 internal relay. Pin 4 connects to one terminal of the receiver's relay coil, pin 5 connects to +12VDC in the receiver's power supply. Pin 7 connects to the other relay coil terminal. Shorting pins 7 and 16 simply "completes" the relay circuit, energizing the relay, MUTING the R599. Remove the short between pins 7 and 16 and the R599 receiver is no longer muted.

Pin 16 is ground. I forgot to mention that. Shorting pin 7 to 16
"complete" the relay coil circuit, energizing the R599 relay, muting the
receiver. You can see this by studying the operator manual's diagram
showing how the R599 is muted when used with a transmitter "other" than
the T599. The transmitter "relay" is shown in "transmit", shorting pins
7 and 16 to energize the R599 relay.

52882. Install second filter for CW in TS820S

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-08-26 16:29:23 UTC
From: lopez@...
Topic: 52882 Message: 52882

Hello friends.
A while ago, I bought a CW filter FoxTango YF88H250 for my TS820S, but once installed, turned out to be very narrow, so it dismounted and bought a YG88C.
I have also made the modification to have CW wide and CW narrow, using the DH switch on the front panel, and everything works well, including digital display, after repair.
My question is, as I have that filter YF88H250 in a drawer, I thought of installing it, to thereby having CW wide, CW narrow, and CW super-narrow. It is possible to do this? If possible, as should be done ?.
Thank you very much for any input.
Best regards from Spain.

Hi Bill,

The short answer is "No"..... lolo...

I am new to this list but I have a number of radios - including a TS520S, but the TS has the best sounding audio in my opinion. The digital ones sound better if you use an external speaker but still not quite as nice.....

The other things you will never get with the new radios are:

- The solid build - big heavy knobs and beautiful machined front panel
- The smell in the shack when you have had it running for a while - that's how a radio should smell...lolo...

Cheers,
Peter - VK2AN

52885. TS520S with an Astatic D101 Mic - strange issue

Yahoo group: TS-520_820_530_830 (2015 — 2016)

Hi Guys,

I have just joined this group but I am feeling at home already as you guys all seem to love the Kenwood Hybrids as much as I do!

I do however, have a strange issue with my TS520S. I have been running it with a Foster Dynamic Mic for some time and it works fine. I recently acquired an amplified D101 lollypop mic and thought it would go well with the Kenwood.

Wiring it up was no problem, but when testing I found a strange issue. When you press the PTT bar on the Mic, there is no Audio from the TS for about 5 seconds, then it slowwly increases to normal level. It does this every time I press the PTT on the Mic. I have checked the Mic output with a CRO and it is fine - it appears to be some issue related to the AGC on the Kenwood Mic input.

Adjusting sensitivity of the Mic and/or Kenwood Mic gain have no effect on the problem.

I have tried adding series and parallel resistors as per the Kenwood manual but it only made a slight improvement.

Has anyone ever come across this before?

Cheers

Peter - VK2AN

Peter,

I ran into this problem way back when I had a TS-520SE in 1980. If you look at the documentation for the rig, you'll see that it requires Hi-Z mike impedance. That is 50K ohms or so. I'll bet if you look at the D101 that you will find it is in the vicinity of 600 ohms or so (Lo-Z). Unless you build an external transformer box -- there are circuits all over the net -- into which you can plug your mike, you won't be able to use the mike.

I posted a few questions and got great responses. Thank all of you! Now for my "Im an idiot" story. I did replace the HV caps as they were bad and just a few others but for the life of me I couldnt get anything out of this radio except grunts and and the squeal rolling up the AF gain. Well, Like I had posted earlier I did see some sparke from the RF board around the 12BY7 tube base. I replaced a few resistors did some clean a lube (I did the VFO as well) but still no love. I wound up breaking the Q5 transistor which was a 2SC1515 so I ordered another one. $1.00 for the part and $3.00 to ship...oh well. Anyway I had the radio facing me from the rear and as I sat there looking I started to think "Something doesn't look right, something is missing". I haven't had this thing out for years but it slowly dawned on me.....The VFO plug was missing. It needs to be shorted at pin 1 & 9 for the internal vfo to work,. I busted out laughing. I remember pulling it some years ago so it wouldn't fall out and get lost. Oh well even with that I expect a little more touch up to be running again.

52888. unable to adjust driver coil in TS520(d) on 40 M

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-08-27 07:30:11 UTC
From: Hans Boon
Topic: 52888 Message: 52888

Dr. members,

I have problems on tuning the TS520 on 40 M using the ALC indication.
On 40 meters, the ALC method works at frequencies well above 7250 kHz
(even at frequencies higher than 7300 kHz), but not in the segmens which
we use here in The Netherlands (7000 kHz to 7200 kHz).
I have tried to retune the driver coil (for now only the coil for 40 M),
but no luck, I can only get an indication on the ALC meter at the
frequencies around and above 7250 kHz.

Any ideas how to solve this, or do I need to retune all driver coils?

Also no ALC on 10 meters, but that seems normal.

Hope someone can help,

73, Hans, pa2hbn

Bill,

If you look on page 10 of the TS-520, page 8 of the TS-520S, or page 7 of the TS-520SE operator's manual you will see which pins must be shorted when the Remote VFO is not plugged into the rear panel REMOTE VFO socket. It doesn't matter what model of 520 you have the same pins, 8 and 9, must be shorted together for the internal VFO to work when a Remote VFO (VFO-520 or VFO-820) is not plugged into the rear Remote VFO socket.

Hans,

If performing the coil pack adjustment doesn't improve your drive then I recommend replacing the driver tube.

Ordinarily you should not adjust any of the coil pack coils out of band sequence or at frequencies other than those listed in the chart in the operating manual maintenance section or the service manual alignment steps. Best practice would be to perform the complete coil pack alignment. Just have to be very careful not to crack a core or rip a former off its mount. I would inspect each ferrite core with good lite before attempting to turn any and if not cracked apply drop of lube at the top of each core before attempting to turn.

Have you tried adjusting the 40 meter Mixer coil before adjusting the Drive coil? If not, do that with the VFO set at 7.150 mhz, Drive control at 1200, Car Pot full CW (heaters on and screen grid switch off). It may be that the 40 meter Mixer coil is not properly adjusted.

If this doesnt help then do the complete coil pack alignment.

I have a procedure listed on my website that will allow you to ensure that the RF Drive peaks at same place that the Receiver peaks at very close to the same Drive Control position. You use the Marker signal or an RF signal generator to accomplish this.

Topic: 52885 Message: 52895
Attachments: 1 described; binary payloads are missing from this source WARC

It's easy to bypass the amp in the base of the amplified D104. Simply remove the bottom cover, there are 3 Phillips head screws then turn the bottom cover over and you should see the schematic wiring diagram of the microphone element, PTT and amp switching, and the amplifier shown as a square with input and output lines indicated.

The following picture shows the amplified D104 base wiring. This should be the wiring diagram you see when you remove the bottom plate on the amplifier D104 base.

To bypass the amp perform the following:
Disconnect the "WHITE" wire from the PTT switch terminal "A".
Disconnect the GREEN wire at the amp and move it to the PTT switch terminal "A".
Remove the battery.

Making the above changes will not let the microphone work in VOX. The microphone will work with PTT as long as you wire the PTT using the "BLUE and RED" wires. To be sure, use an ohm meter to check the PTT wiring. Unless you are the original owner of the D104 microphone, you won't know what a previous owner has done to the wiring. Do not assume the wiring is correct, check it with an ohm meter to be sure. Pay attention to the MIC element wires, do not connect the ohm meter across the microphone element wires!!

To bypass the amp and allow the microphone to work in VOX do the following you do not have to disconnect the "WHITE" wire from the PTT switch terminal "A", just do the simply change below:

Disconnect the GREEN wire at the amp's input and move it to the PTT switch terminal "B". The microphone element is now wired directly to the microphone cable, not through the PTT switch. You do not have to press the PTT button for VOX, simply turn the VOX switch ON and talking into the microphone.

All this assumes you have paid attention to the wire colors and wired the 4 pin microphone plug "correctly" according to your KW hybrid operating manual's microphone plug wiring. The main schematic of the KW hybrid also has the PTT and microphone element wiring.

The above wiring shows the PTT switch in "receive", PTT bar is not pressed. The Arrow shows the direction of the switch movement when the PTT bar is pressed. Therefore, PTT wiring to the KW hybrid 4 pin microphone socket can use wire colors RED and BLUE. The "RED" wire is

connected to pin "2" and the BLUE wire is connected to pin 3. The microphone element "Hot" wire is "WHITE" which is shown connected to the PTT switch terminal "B". Connect this WHITE wire which is the center conductor in the shield, connect this wire to pin 1 and the shield to pin 4.

I see no reason to run the mike element connection through the push-to-talk switch in your third paragraph. Just wire it for VOX operation as shown in your sixth paragraph. If you're not using VOX, turn VOX off or the control down to zero. Push-to-talk will work fine (push and talk). This way the mike is wired for both functions. As indicated, remove the battery.

Disconnect the "WHITE" wire from the PTT switch terminal "A".
Disconnect the GREEN wire at the amp and move it to the PTT switch terminal "A".
Remove the battery.

Making the above changes will not let the microphone work in VOX. The microphone will work with PTT as long as you wire the PTT using the "BLUE and RED" wires. To be sure, use an ohm meter to check the PTT wiring. Unless you are the original owner of the D104 microphone, you won't know what a previous owner has done to the wiring. Do not assume the wiring is correct, check it with an ohm meter to be sure. Pay attention to the MIC element wires, do not connect the ohm meter across the microphone element wires!!

To bypass the amp and allow the microphone to work in VOX do the following you do not have to disconnect the "WHITE" wire from the PTT switch terminal "A", just do the simply change below:

Disconnect the GREEN wire at the amp's input and move it to the PTT switch terminal "B". The microphone element is now wired directly to the microphone cable, not through the PTT switch. You do not have to press the PTT button for VOX, simply turn the VOX switch ON and talking into the microphone.

All this assumes you have paid attention to the wire colors and wired the 4 pin microphone plug "correctly" according to your KW hybrid operating manual's microphone plug wiring. The main schematic of the KW hybrid also has the PTT and microphone element wiring.

The above wiring shows the PTT switch in "receive", PTT bar is not pressed. The Arrow shows the direction of the switch movement when the PTT bar is pressed. Therefore, PTT wiring to the KW hybrid 4 pin microphone socket can use wire colors RED and BLUE. The "RED" wire is connected to pin "2" and the BLUE wire is connected to pin 3. The microphone element "Hot"

wire is "WHITE" which is shown connected to the PTT switch terminal "B". Connect this WHITE wire which is the center conductor in the shield, connect this wire to pin 1 and the shield to pin 4.

Actually, on a D-104, it is more correctly put as, “Grab and Talk”! <<GRIN>>

I see no reason to run the mike element connection through the push-to-talk switch in your third paragraph. Just wire it for VOX operation as shown in your sixth paragraph. If you're not using VOX, turn VOX off or the control down to zero. Push-to-talk will work fine (push and talk). This way the mike is wired for both functions. As indicated, remove the battery.

I don't either Pete but I thought I would provide both methods of bypassing the amp for those who are not aware the microphone element is wired through the PTT switch.

I use a non-amplified D-104 with my Drake B and C lines, my Heathkit HW-101 and SB-100, and a Johnson Messenger 223 I modified for VFO (N3ZI DDS VFO) control on 10 meter AM on 29Mhz. All 3 microphones have the microphone element wiring changed in the base so the element doesn't go through the PTT switch.

If you feel the lube becoming "Gummy" might be a problem, try using full synthetic clock oil. It will not congeal and will penetrate better then any mineral oil. Another consideration is PB Baster anti seize solvent, available at any automotive parts store.

WD-40 is primarily a water displacement solvent. It is an unremarkable lubricant or anti seize product. It's primary ingredient is fish oil.

We are talking about a drop or two at the most on the tip of a sharp pointed toothpick or tip of a small artist paint brush. Trying to use it more as a "penetrating" oil and not for bearing surface lubrication. Just want it to wick or leach between the core threads and the inside surface of the cardboard former tube.

Some people apply the tip of low wattage soldering iron to the core to free it, but I wouldnt do that unless a drop or two of oil is tried first. You can see it run around the top of the core and leach down inside as you apply it. 3-N-1 or sewing machine oil would be fine. Any light weight should work.

I would not use Bolt Blaster or Kroil oil or any kind of true Penetrating oil as they all have a very strong odor that could linger in the radio.

A licensed member is not required to include their call sign along with their name when signing messages they post.

Example:

If the member's name is George and his call sign is WA6ZZZ, the member has 2 message signature options:

1. They can sign their messages with:

"George WA6ZZZ"

or

2. They can sign their messages with:

"George"

without the member's call sign. Whether the member uses "73" or not is entirely up to the member.

The following text was taken from the recent group policy update earlier this year that can be found in the group's Files section folder labeled "AUTOTEXT MSGS", in the file named "Messages on approved membership.txt".

"If a member does not wish to include their Amateur Radio call sign in their signature then simply use their first name ONLY, same as non-licensed members"

Thanks for the replies guys but I think I have partially solved the issue. It only happens with the compressor on - turn it off and it works fine. It appears the "thump" when the amp turns on upsets the AGC in the compressor.

I understand that the mic is wired through the PTT switch and that the VOX will not work, but personally I hate using VOX so that is not an issue. The main reason for using the amp in the mic is that I am told the amp adjusts the output impedance and therefore gives a better high frequency response, however, you guys may be right and it might just be a lot easier to bypass the amp and PTT switch.

Cheers,
Peter - VK2AN

Hello Terry,

I did not touch the mixer-coil, just the driver coil.

I give the mixer-coil a try. Since the ALC reading for tuning is OK on 20 meterband I don't expect the drivertube to be bad.

Do you think the frequency to adjust the coils should be 7100 kHz here in Europe since we now have the 40 meterband from 7000 to 7200 kHz and the adjustmentfrequency would be just the middle between de bandedged. (like the 7150 kHz for the full 40 meterband in the USA (7000 - 7300 kHz.)

The alighment paper on your site makes things a lot more clear to me wrt the alignmen.

Thanks for your answer.

Topic: 52910 Message: 52910

Greetings group,
Some more clarification is in order. Yesterday, Mike-w5rkl, posted to the group, information regarding the Group Policy regarding signing of posts/msgs. TNX Mike. The requirement of including your call sign (if any) was deleted about 1 year ago and the "welcome msg" was also updated to reflect changes to the overall Group Policy.In short, you are REQUIRED to sign, at the end of any/all posts/msgs, with at least your first or Christian name. NO EXCEPTIONS. Many first/Christian names are common....ie: "John, Mark,....etc...so IF you also have a call...it would be nice...but NOT required if you also include it in your "signature,"and if no call, maybe a geographical location..."Joe in Washington State," again, NOT required, but nice.

There are members of this group that have an interest in what we do, but are not a Licensed Radio Amateur Operator, we welcome them...and as stated prior...since they do not have a call...see above....
Every new member to this group is automatically sent a "welcome message," clearly stating the Group Policies. I can not remember how many times when a new(er) member is advised of the need to adhere to Group Policy, the reply is usually; "I'm new to the group and did not know."
Also, as stated many times before, you can set your email program to automatically add a "signature" at the end of every post/msg, Yahoo included...
I hope some misunderstandings have now been cleared up. Thanks to all group members for making this the place to go for your KW hybrid needs!
I now lower my soap box..and return you to your regular programming.....

Hans:

Adjusting the coils at the listed frequencies and band sequence allows the peak in Rx sensitivity and Tx RF drive level to occur with the three Drive Control air variable capacitors at the 1200 position which is approximately half mesh or half of the capacitance value. This ensures there is enough minimum and maximum capacitance available for both extreme ends of the VFO tuning range.

I would just literally follow the alignment chart in the Service Manual or in the Maintenance section of the Operating manual.

If after performing coil pack alignment you still cannot obtain any ALC indication on just the 40 meters band you could have a bad Drive coil, bad Drive coil solder connection, or a bad bandswitch contact which is a little unusual on the 520 series. More common to have frozen or cracked cores and or coils twisted off the mounts. I am assuming you can peak 40 meters Rx with the Mixer coil.

Can you load the radio on 40 meters? It is possible to have low rf drive at the 6146 control grids and have no ALC indication in Tune mode but still have RF output power. Can you peak the Drive on 40 using the RF relative power position of the panel meter or on an external wattmeter? Anything less than approx 39 rms RF volts and you will have no ALC indication as you wont be able to overcome the offset of the operating bias and produce grid current on positive swing of the RF drive envelope. No grid current means no ALC indication.

If you have a means to measure RF voltage levels can pretty quickly see where RF drive is low or missing. At the control grids of the 6146 final tubes should see approx 45 rms rf volts.

At MD you should have approx 2 rms rf volts. If you do that means TX mixer and control grid of 12BY7A Driver tube is seeing the 40 meter Mixer coil/capacitor tuned circuit. While monitoring RF voltage at MD you can adjust the 40 meter Mixer coil to see if you can peak the RF voltage as you turn the core. If you have approx 2 volts them move on to DRV and see if you have high 50s to low 60s rf rms volts.

52914. Kenwood Hybrid Net Update (August 30, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-08-30 22:45:04 UTC
From: Mark Gilger
Topic: 52914 Message: 52914

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday net was run by me, WB0IQK. There
were 11 stations checking in under poor
conditions. We had the following number of radios checking in.

2 running TS-520(x)
2 running TS-530(x)
0 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS900

The rest were running non Kenwood hybrid equipment.

He was running my Drake TR=7 & L4B amplifier.

The Sunday net was run by me, WB0IQK. There were
10 stations checking in under poor
conditions. We had the following number of radios checking in.

1 running TS-520(x)
1 running TS-530(x)
0 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS900

The rest were running non Kenwood hybrid equipment.

I was running my Drake TR-7 + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total = 142, Sunday☐s total = 88
December 2014, Saturday☐s net total = 92, Sunday☐s total = 86
January 2015, Saturday☐s net total = 110, Sunday☐s total = 84
February 2015, Saturday☐s net total = 103, Sunday☐s total = 98
March 2015, Saturday☐s net total =80, Sunday☐s total = 51
April 2015, Saturday☐s net total = 59, Sunday☐s total = 29
May 2015, Saturday☐s net total = 79, Sunday☐s total = 48
June 2015, Saturday☐s net total = 70, Sunday☐s total = 38
July 2015, Saturday☐s net total = 26, Sunday☐s total = 56
August 2015, Saturday☐s net total = 73, Sunday☐s total = 65 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:

John...K8JD
Good to hear that someone (using a Kenwood),
is still working C.W.
I thought I was a loner.
Have done C.W. since 1958,
C.W. is the REAL THING in Ham Radio.

I do have a pair of nice mikes that came with this second-hand TS-830,
but they are in a nice box way up in the attic somewhere.
This Kenwood is a really nice Cadillac of a rig.

I prefer my 1940 Bug and operate generally at 10W , 20M,
into a 225 ft LongWire.
I do lots of listening, copying in my head,
catching the weather from all around,
the family story, the general ham stuff.

Justed turned the 830 on, 20M, 10W, hearing two hams 300Hz apart,
attached my homebrew CW signal processor,
and now have picked one signal to copy.

CW and my old Bug help me feel like I'm 21 again ... for a while.
Good to hear the K8JD story .

52916. Kenwood VFO 230 US transformer

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-09-01 10:33:54 UTC
From: pa3cev@...
Topic: 52916 Message: 52916

Someone sold me a US version of the VFO 230, the only difference to a EU version is the mains transformer which is just 120 Volts, no taps for 220 on the primary. This VFO has been used by the former owner on 220, which is clear looking at the power supply board.

Anyway, I removed the main PCB and measured the secondary windings, 10 volts and 22 volt, so I presume the normal voltage should be around 5 and 10 volts. Can anyone confirm this?

Now I'm looking for a solution, maybe someone has a original EU tranformer on spare???

From: dearl1953@...
Topic: 52916 Message: 52918

Eric

The power consumption of the VFO-230 is very low, only 13 watts. Why not simply buy a small step down transformer? Anything 20VA capacity or bigger should work fine. Mount in and enclosure with a US style receptacle on the output.

This way you can avoid the hassle of modifying the VFO

From: tjb813@...
Topic: 52917 Message: 52919

What are you using as indication that it doesn't transmit?
Does it transmit in CW and not SSB? or the opposite? Or neither?
Do you have ALC indication when tuning in CW?
Do you have Plate current readings when attempting to transmit in CW?
History of the radio?
Did the radio work before and suddenly quit?
Has it been in long storage?
What is different now from when it last worked?
Smoke? Noises? Repairs?

A little more information will yield a prudent path to trouble shooting. Simply "it doesn't transmit" only leaves about 150 different possibilities. The SG switch being one of the most common.

Radio came from an SK estate, had sat idle for about 20yrs. Recapped, replaced Q3 and Q4 on the AF unit and got receive working. I never powered it up until after I recapped. SKs son stated it was all working when his dad SK.

Using a dummy load with a heathkit HM102 in between.

I get 60ma at idle plate current.
I am at the drive tuning state on page 21 of the manual.
Not getting any drive indication on the meter when set to ALC with settings as described on table 2 of the manual.
Same when I try and use CW or SSB, no drive indication.
No ALC on CW.
I replaced the drive tube. 12BY7A.

Thanks for your help.

OK,great, now with that info we can start to isolate the areas to look for.

I can assume you have the drive control turned up.

As an after thought, just so we don't chase out tales, have you cleaned the band switch and mode switch wafer contacts? With age (storage) these oxidize and can cause intermittent operation. The last wafer of the band switch is for the driver output to final grid input. If that has been done, then we need to "dig in".

As a general test, check the voltage from the AVR board. See if they are within spec.

The HET oscillators are working because the set receives.

So with no ALC you don't need to focus on the finals (yet). No ALC (no drive per se) means we can start with a focus on the generator section and follow it from there.

If you have a FREQUENCY COUNTER see if you get readings from the HET, Carrier, and VFO outputs on the back of the rig. The connections are for the DG-5 display. I am most interested in the CAR. That should change frequency as you change the mode from LSB to USB.

If you have those, then I would look at the Ballanced mod board next. Check voltages.

If all that checks, then we look at the IF and mixer circuits.

A good scope and the service manual will be invaluable. The service manual is available free on-line. One site has expanded schematic drawings that are easier to read.

Keep us informed as to what you find.

If he has an O-scope or RF millivolt meter and the TX Level Diagram in a matter of minutes can determine where RF drive is low or missing and then do things such as checking DC voltages and LO signals etc.

I dont understand why people dont understand and use this troubleshooting tool that KW provided us?

Suggest look at TP-2 on RF board to see if have TIF signal of approx 250mv. Very seldom is loss of TIF the problem. If TIF is good then move to MD and look at output of the TX Mixer. It should be approx 2 to 3 rms RF volts. It is almost like shooting fish in a barrel.

Nothing wrong with checking RF-1 level (3.2vdc) at the AVR board and making sure that ALC bus is being energized when the Aux control relay changes state. At the RF board ALC will measure approx 2.6vdc with 10 or 11 meg ohm meter. Should see same at AGL wire wrap post on the IF board when flip to Send. Accessing and removing Aux Control relay for contact cleaning is pain in the butt so I wouldnt do it until confirmed that dont have good ALC bus voltage.

Again after exhausting the simple experiencial based stuff (SG switch on etc) then always always reach for the TX Level diagram and measure RF voltage levels from TIF to control grids of 6146 finals. Cant get any easier to focus your troubleshooting efforts.

Topic: 52917 Message: 52930

One more reminder which I have mentioned dozens of times DO NOT attempt to measure RF voltage level at DRV or 6146 PIN 5 Control grids with standard single diode RF probe (O-scope is fine). Will exceed the PIV of the diode and blow it. See message #42072.

Other questions that come to mind:

1. Have you attempted to load the radio beyond peaking the ALC indication in Tune Mode?

2. If you place the rig in CW mode can you tune the tank to resonance (dip the plate current)? Do this quickly.

3. If you place the meter in RF relative power position and mode to CW and CAR pot full CW can you get any indication and peak that meter deflection with the Drive control?

It is possible to get RF output and load the radio and have no ALC indication at that initial loading step. On a TS520 you need greater than 39 rms RF volts on 6146 Pin 5 control grids inorder to have any ua grid current and resulting ALC indication. If you have 37 RF volts you will be able to load to approx 100 watts output and have no ALC indication.

It is of course possible that you do not have low RF drive and actually have no RF drive, but unless you measure you are just guessing. This can result in a lot of wasted effort and time. As has been stated here over and over again first recommended test gear is VTVM and RF probes (single diode and 3 diode).

Carlos stated the IP meter displayed normal 60ma no RF drive final amplifier class AB1 idling current. This, in itself, clearly indicates the SG switch has to be in the ON position. If the SG switch were in the OFF position, Carlos would have seen the meter resting at zero (meter switch set to IP) regardless of the transmit mode.

If the SG switch is set to OFF, tuning the transmitter drive control for a peak ALC indication will still occur. This is because the SG switch has no control over grid current flowing in the 6146s. If you want to verify this simply perform the following simple test:

1. Connect your KW hybrid to a 50 ohm dummy load.
2. Set the HEATER switch to ON if your KW hybrid has a HEATER switch and power up your KW hybrid.
3. Set the SG switch to OFF.
4. Set the MODE switch to TUNE.
5. Set the meter switch to ALC.
6. Set the CAR control to 10 o'clock.
7. Key the transmitter with the SEND switch.
8. Adjust the DRIVE control and notice the rise in ALC meter indication. If meter pegs fully to the right reduce CAR control setting "CCW" to reduce drive so the meter pointer is pointing at 12 o'clock.
9. With the transmitter still keyed change the meter switch to IP and note the meter is resting at "zero"!
10. Unkey the transmitter.

The SG switch simply changes the 6146 screen voltage from approximately +260VDC in the ON position to approximately -101VDC in the OFF position. That's all the SG switch does! The SG switch setting has nothing to do with nor does it control the flow of grid current (ALC produced) in the 6146 final tubes. There will still be ALC produced and indicated on the ALC meter even with the SG switch set to OFF.

The SG switch set to OFF, the 6146 screen voltage is approximately -101VDC. Voltage source is the Rectifier Unit's -C bias supply.

The SG switch set to ON, the 6146 screen voltage is approximately +260VDC. Voltage source is the Rectifier Unit's 210A supply.

Then why come here and ask for help?

Should we limit the forum to asking questions about what accessory will work with what rig or how to load or how to install attenuator pads to drive linear amps?

Would you have Joe limit all troubleshooting responses to "Is the 8/9 jumper installed?" or " Is the SG switch on?" (which was misguided as he stated that he has 60ma resting plate current).

Nothing wrong with directing the Op to check the simple and experiencial based items first. Those things along with correcting operator error can often fix the issue.

However, there is a point if you own and plan on maintaining your KW hybrid that you need to establish a modest test bench and start learning how the radio works. If interested and you have the aptitude there are people here willing to help you learn how the radio works.

There is nothing complex about running the TX Level Diagram when you have low or missing RF drive. A VTVM and RF Probe are basic tools. It is about as simple and fundamental testing that can be done and we are fortunate that KW provided normal levels in the Service manual which not many manufacturers did.

I have discussed the safety risk assessment and safety risk management actions associated with servicing these radios many many times on this forum. You can keyword search to confirm that. Try 52433 most recently.

Terry,
I just checked with the wife. It is ok for me to use the light switch to turn on my radios, but in no case am I to even mentally imagine opening the case. For that, she wants me to buy a million dollar life insurance policy, then wait for her to help (that last part worries me)

I mean no disrespect but there are many members who have no clue how their KW hybrid works inside. This doesn't mean they only need to know what knob to turn, what meter indication to look for, or how much RF you should see on your handy dandy relative power watt meter. What this means is, if you plan on servicing your own ham gear you will need the following:

1. Have basic and some advance electronic knowledge including skills and knowledge troubleshooting electronic circuits.

2. Have basic test equipment including analog VTVM with RF, AC, and DC probes, simple frequency counter, simple signal generator, and oscilloscope with probe.

3. Have a solid working knowledge how to use items in #2

4. Have studied the service manuals and can trace a circuit by reading and understanding the schematic

5. Have a solid understanding of how both TX and RX signals are processed in your KW hybrid or other ham gear (what each stage in your KW hybrid does and how it works with other stages to process both TX and RX signals).

6. Have a solid understanding of the Safety precautions required when dealing with AC, DC, and RF voltages at all levels!!!

We have provided over the months and years, numerous reference materials/books for those hams who want to learn. We can only provide the material for you, it's up to YOU to spend time studying the material. We can't hold your hand throughout the entire process but we can do our best answering questions on subjects you are not sure of. Don't jump ahead to advance subjects/chapters until you have a "solid understanding" of the basic. Doing so will make understanding the advance topics/subject difficult if not impossible.

I mean no disrespect but those who want to learn have to do their part.

Carlos:

I wasnt directing comments to you about " why coming here" to ask for help. I was directing them to the other gentleman who said what I was asking was too hard for many and many dont have even modest test gear and it can be unsafe.

If a person recognizes their limitations and doesnt get under the hood of their KW hybrid not a thing wrong with that. In that case it is the absolute best and safest thing they can do. Prevents them from damaging or inducing a fault in the radio and prevents them from getting hurt or worse. Certainly no shame in that whatsoever.

You apparently read DC bias voltages at TP-2 and I was telling you to read RF signal voltages at TP-2 and MD and not DC voltages. RF voltages are AC and not DC. At TP-2 you will measure the TIF or Transmit Intermediate Frequency signal. RF is AC or alternating current at a very high frequency or RF (radio frequency) rate. In this case at 8.830 mhz. Your O-scope is ideal instrument to measure the TIF signal. It will be around 200mv.

Although an O-scope is harder to use than a VTVM and RF probe for RF signal measurements as you must not only select the vertical amp input type and level you must also select the time base and sync. If you are rusty using an O-scope suggest you obtain VTVM and RF probes.

Best way to troubleshoot low or missing RF drive (as evidenced by no ALC indication when attempting to load) is to measure the RF drive levels in the transmit chain to see where the signal is low or missing. Once you know where that is at you can then do things like measure Drain, Gate, Source or Collector, Base, Emitter dc voltages at an involved active device (mosfet or transistor) and confirm that Local Oscillator signal is present.

If you measure approx 200mv-250mv of TIF signal the next place to check is at MD which is the RF output from the Transmit Mixer and the input to the Driver tube control grid. This is the first place that you will see the actual transmit frequency. It is produced by mixing the TIF signal and the HET Osc signal. The HET is what is called the Local Oscillator or LO and is high level around 1.0 RF volts which you can measure at TP-3. From the TX Level Diagram you can see that the RF drive level at MD will be at least 2 RF volts.

What I was hoping you could do is take the TX Level Diagram RF voltage readings and then report back. Where you find RF drive to be very low or missing we could discuss the next step in troubleshooting.

I am sorry I stuck my nose in here. Didnt mean to hijack the thread but it always frustrates me when people try to help someone and there is no mention of running the TX Level Diagrams which should be standard practice.

Carlos:

I forgot to ad that you are not concerned about measuring frequencies of any kind with your O-scope at this time. It is normal to read different carrier oscillator frequencies with your scope when looking at LSB and USB. Adjusting the LSB and USB carrier osc trimmers can be covered later when you are interested in setting the carrier set point for the kind of audio response you want. Right now you need to focus on where RF drive is low or missing and then troubleshooting that stage or device.

Some people prefer to start at control grids of the 6146 finals and work their way back to the TIF. That is OK. Just have to exercise caution working there as in proximity of high voltages. As I previously mentioned it is rare to have no TIF signal but it can happen.

If you find you have no TIF signal at the RF board then you go to the IF board and measure at the TIF wire wrap post and if none there then make sure TBL is there biasing on Q2 and then making sure have IF at TP-1 and making sure have ALC bus voltage at AGL and so on and so on back down the chain toward the Balanced Modulator on the Gen Board.

There should be no reason you would be measuring any signal frequencies at this stage of troubleshooting.

52940. TS-830 Alignment Question

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-09-05 00:10:31 UTC
From: Robert Fish
Topic: 52940 Message: 52940

Hi Guys,
Quick question, I am running through the alignment procedure on a working TS-830. Step 9 in the service manual alignment procedure involves measuring frequencies and VCO voltages for all the bands at 0....250...500 on the VFO. It doesn't mention a spec for frequency or for the voltage. The reason I ask is, my VCO frequencies are all 1.5Khz high i.e. 18 Mhz band is 26.8315 at 0 on the VFO 27.0815 at 250 and 27.3315 at 500.
The VCO voltage is 1.55 Khz high for all bands and all VFO positions. The freqs are called out only two places to the right of the decimal so does that mean I don't have to worry about any finer resolution?
There is no spec for the VCO voltages either as far as I can see, maybe I am missing something. Like I mentioned this radio works, it is right on frequency. I am just running through the alignment to familiarize myself with the radio and to tighten up anything that may have drifted over the years

Thanks,

Bob K6GGO

Mike:

Your list there was what I always knew as the dictionary DEFINITION of an amateur radio operator....

My, how times have changed.

Ran into an "Extra Class" license holder the other day who didn't have clue ONE about anything electronic, not even Ohm's Law. He memorized the test bank - apparently so he could buy a large linear amplifier from an ethical dealer who wouldn't let him have it to hook up to his Childrens Band rig.

But this isn't Kenwood / Hybrid related so I'll drop off here with the hopefully on-topic comment of "Check the relays."

Sounds like one of the 'experiential failure points' that isn't getting covered much in this thread. I seem to recall Terry mentioning it, or possibly you, Mike. But from diving in the list archives it seems to be one of the more probable points of failure for this particular symptom.

If any of the more experienced hybrid techs ("I am only an egg.") on here disagree, I will certainly bow to their superior knowledge. But it might bear looking into.

Your frequencies are fine. You need approx 1 volt of VCO (LO for the TX and RX mixers) for good mixer action. The VCO level is listed as 1 volt +3dB/- 2dB which means 794mv to 1.412 volts. This is measured at the RF board at TP-3. The voltage will vary as you run the VFO lock to lock and the display should not blank at either 0 or 500.

I clearly stated that the RF-1 voltage be checked at the AVR board and ALC bus voltage be checked at the RF and IF boards and even gave the level that a 11 meg meter would pull it down to. I suggested this be done before the Aux Control relay is pulled and contacts cleaned as it is pain in butt to access it. Yes it is one of the "experiential" based items that should be checked.

Of course my definition of "clearly" apparently was only clear to me. Kind of like when I speak to my wife. I said and she heard!

Thanks Terry,
Good news on the frequencies. I saw the the spec for output voltage 1 volt +3dB/- 2dB. I was talking about the spec for the DC voltage at TP1 on the PLL board. The voltages are called out in parenthesis and adjusted with T1 through T6 on the PLL board. I don't see a spec for how close those have to be. A few of mine were a fair amount off. If that is the VCO control voltage, it would seem critical for it to be right on the money.

After looking at the schematic (always a good idea), I was confused about how this adjustment worked. It looked like the Transformers T1 through T6 were frequency determining components of the six VCOs. How was changing the inductance of those transformers changing the VCO control voltage, but not the frequency of the VCO itself? Then it occurred to me that this is a loop. The transformer is changing the resonant frequency of the VCO and the PLL is changing VCO control voltage to keep the frequency the same. SO, this adjustment just keeps the thing in the middle of its range so it doesn't blank out (lose lock) at one end or the other of the VFO travel.

That would explain why the VCO control voltage (the one in parenthesis in the service manual step 9) isn't critical.

Am I on the right track?

Thanks,

Bob K6GGO

Guys,

I agree absolutely. I am a member of the Icom7600 group also. If you have never been on this group, I'll give you some idea of what is discussed. There were over 60 messages about "what features we want in the next firmware release" and I have just finished wading through at least 30 messages about "which brand of microphone is best" with (of course) Heil coming in number one..... I think I am going to cancel my subscription before I die of complete boredom.... it appears owners of 7600's never build or repair anything?

Its so refreshing to see some great posts from knowledgable guys about how transceivers actually work and how you can actually troubleshoot and repair one yourself. Isn't this what ham radio is really about? I really hope this group doesn't degenerate into the "mine cost more than yours so it's better" and "throw it away and buy the latest one" mindset!

Cheers and 73's

Peter - VK2AN

Bob:

Yes T1 thru T6 are the tank inductors in the Colpitts oscillator circuits (both BJT and FET oscillators) and you are adjusting the resonant frequency of the VCO tank circuit when you tune them, but KW doesnt have you adjust them for the resonant frequency that you see listed in the chart. They have you use a DMM and adjust them until you have the noted DC Control or Tuning voltage that is in the parenthesis. This as you note ensures that the Tuning voltage is in the required range. Most common config is for an increase in Tuning voltage to produce an increase in VCO frequency, but you can see from the chart and measuring that dependent on the band that isnt always the case.

Looking at the schematic you can see that Q17 contains the Charge Pump and the Loop Filter that converts that current pulses to voltage is an Active filter consisting of Q18 thru Q20 along with associated RC components. An Op amp active filter would be more commonly used.

I just try to adjust T1 thru T6 with VFO at 250 to close to the listed DC voltage to two decimal places. With exception of 10 meters which is performed in middle of the band range with VFO at 500. No good reason, but I tend to set them a few tenths of a volt high rather than lower than the listed voltage as they tend to drift off lower.

When I am done I swing the VFO on each band and make sure that the VCO signal voltage at TP-3 on RF board is varying and that digital display doesnt blank. Never had a problem with this. Most common problem is bad solder connection at the VCO cable male and female end connectors both center pin and shield and at the solder pads on the PC board mating connectors.

Terry, no biggie.

OK I found the heathkit RF probe. Now which is a better meter to use the IM18 or the bench IM25. This all came from the estate I purchased.

I did a quick check with the RF probe on TP2 in send and I get a very very slight deflection with the IM18 set to AC and 1.5

Need to run. More this evening.

Thanks
Carlos

OK this is getting nutty. I am fully aware that if Carlos has receive mode then he must have RF-1 as RF-1 is the Reference Voltage that supplies the AGC and ALC bus or rails. I understand that RF-1 is not mode dependent.

Yes if the AGC bus was dead he would have no receiver and a pegged S-meter. I simply suggested that he measure RF-1 and make sure it was set to proper level before moving on to measure ALC bus voltage when flipped to Send.

I still stand that after exhausting the simple experiential based items like screen grid switch on,8/9 jumper in place, heater switch on etc. then the most efficient and fastest way to find where RF drive is low or missing is to run the TX Level Diagram.

If others want to start taking random resistance readings, random dc voltage readings, frequency counter measurements of various oscillators then have a ball.

If you want to pull both RL-1 relays and clean the contacts that is fine and probably a good idea if the radio has set for a very long time.

One of the things about performing multiple "fixes" without checking after each individual one is if the problem is remedied you may not know what fixed it. Pretty hard to learn that way.

Carlos I have given you all the help I can. Someday when I get the time maybe I will make a video and post it on my website to show folks how to run the TX Level Diagram and what very low or very high RF voltages readings mean.

For those folks like Bob who are going thru the service manual alignment it isnt something you do in lieu of troubleshooting or as a routine practice as you can wear out adjustment devices and/or break things. Bob is doing it to re-base line his radio and to learn. To him I would recommend when he is done he should run the TX Level Diagram on 20 meters while his TS830 transmitter is fully functional and in good state of tune and record his RF drive voltage levels for future reference. It will not only familiarize him with the test points, but instrument effect as well.

Carlos:

Why set the IM-18 to AC?

The RF probe is a diode detector. It takes the RF drive voltage (an AC signal) and rectifies it and produces a negative DC output from the probe.

You need to set the IM-18 to -DC and 1.5volt range. You will read on the black 0 to 15 scale. Should read around 2 which is 0.2 volt or 200 millivolts.

Change the IM-18 range switch to 5vdc and move the RF probe to MD on the RF board and read on the black 0 to 50 scale. Should read around 20 or more which would be 2 volts. If the reading is low try varying the Drive Control to increase it.

Assuming your IM-18 and RF probe are good you now have the right test gear to measure RF drive levels at TIF and MD. DO NOT move the probe to DRV or control grids of the 6146 Finals as you can damage the probe. It can be done if the CAR pot is turned down and then slowly turned CW as you monitor the voltage level not to exceed approx 30 volts, but I dont recommend it unless you have some experience. Far safer to use a 3 diode probe.

Carlos:

One last thing I assume you looked at the TX Level Diagram in the Service Manual and have the radio configured properly to take the RF voltage level readings?

If not, for your first attempt do this:
1. Place rig on dummy load (a good practice)
2. SG switch Off
3. Band 14
4. VFO 200
5. Mode CW
6. Heaters On
7. Drive Control 1200
8. CAR Level Pot full CW
9. Flip to Send
10. Check TIF level at TP-2
11. Check level at MD (if level is low try adjusting the Drive Control to peak the reading)

If you have good TIF and low or no MD then repeat at 7.200. The lower you run the TX Level Diagram the less your RF probe or Scope probe will influence the readings. The higher you run them the more the capacitive reactance of your probes shunt capacitance will detune the involved grid and plate LC circuits being switched in by the bandswitch.

Carlos:

You must turn the screen grid switch off. NO REASON to have the Finals powered and have long key down times taking RF drive readings. I am quite certain that I gave you the radio config for running TX level diagram. In fact I know I told you to run the TX Level Diagram in CW mode with the SG switch off.

For ALC indication you only need the heaters on and cathode emission from the finals. You dont need any plate current. Hopefully you havent burned up your PA cage or 6146 final tubes.

You need to read the Service Manual with more attention to detail. Section 3-9 describes the Level Diagrams and clearly states to turn off the SG switch.

I would check the IM-18 using a battery to make sure it is functional measuring dc voltages. Do that with the probe switch flipped to DC position.

I would also check the RF probe to make sure it has a good diode. Can do that by measuring RF at places like TP-3 on RF board (HET osc output should be approx 800mv to 1.0 volts) or measure the VFO rf output voltage at the IF board where it will also me close to 1.0 volts.

I assume you have a 309C probe, but it could be a PK-3 Probe. If the latter you wont be able to read TIF with it because the barrier voltage of three series connected diodes limits how low an RF signal you can read. You may want to remove end cap and look in at the pc board to see if you have one diode or three diodes to confirm which probe you have it the label is worn off.

Again the IM-18 and RF probe combo is typically easier for newer folks to master than an O-scope. The O-scope will need to be used if you have to go to the IF board to measure TIF level.

If you in fact only have 380mv at MD that of course is not good. Sadly this long distance troubleshooting method doesnt give me much confidence that that measurement is accurate. Everything is based on accurate information.

If you really do have 380mv of drive at MD then can do several things:
1. Repeat the measurement on another band ie try at 7.200mhz instead of 14.2mhz
2. Look at TIF at TP-2. Is it approx 200 to 250 mv? Assuming there is some level of TIF at TP-2 try peaking it by adjusting T1.
3. Even though I assume you have good receive measure HET Osc level at TP-3 in TX mode. It is the LO for TX Mixer and should be close to 1.0v.
4. Go back to IF board and measure TIF. Will need to use O-scope for this low level signal (approx 35mv)

As I previously mentioned I need to move on now. I am afraid I am doing you more harm than good. At this point if you have read my responses you should not be blowing fuses. My responses are apparently too cryptic.

Carlos:

I think in order to help yourself and to help others who are following this thread and want to jump in and help you that you validate for yourself and all of us that your O-scope is working and you know how to use it.

All follow up advise and direction is based on having a confidence level that the measurements that you report are accurate.

One way to do that is for you to measure the rf voltage levels of the HET Osc and the VFO and report back. Report the Peak to Peak voltages.

This medium is limited to only being able to Tell. We cannot Show. We cannot Observe. We cannot provide Feedback or Coaching. It is very important that you can read with comprehension and follow directions. Telling is of course not the best Training Method and Telling in written medium is labor intensive.

So I and others will gladly share our time, our knowledge, and our experience, but only up to a point.

Assuming you can re-fuse your radio and it will hold I suggest you take the above two readings and report back and if the P-P levels appear reasonable we can then proceed with TX Level Diagram measurements with a level of confidence that the reported as found rf drive levels are accurate.

Lastly, I still do not know if you have measured the ALC bus voltage with your IM-18 or not? If the ALC bus is not energized you will have no dc control voltage to the gain controlled devices and there will be no RF drive level to measure at TIF. This is this business of checking one more experiential based item ie the RL-1 aux relay contacts that I believe Will suggested.

52955. Hybrid net update (September 6, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-09-06 19:01:41 UTC
From: Mark Gilger
Topic: 52955 Message: 52955

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm
The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by me, WB0IQK. There
were 18 stations checking in under good band conditions.

We had the following number of radios checking in.

2 running TS-520(x)
2 running TS-530(x)
4 running TS-820(x)
4 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running a Drake TR-7 with my L-4B AMP.

The Sunday net was run by me, WB0IQK. There were
6 stations checking in under fair Â good
conditions. Â We had the following number of radios checking in.

0 running TS-520(x)
1 running TS-530(x)
0 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900Â

I was running a Drake TR-7 with my L-4B AMP.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940â□□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturdays net total = 142, Sundays total = 88

December 2014, Saturdays net total = 92, Sundays total = 86

January 2015, Saturdays net total = 110, Sundays total = 84

February 2015, Saturdays net total = 103, Sundays total = 98

The probe is a PK3.
With the radio set to:

If not, for your first attempt do this:
1. Place rig on dummy load (a good practice)
2. SG switch Off
3. Band 14
4. VFO 200
5. Mode CW
6. Heaters On
7. Drive Control 1200
8. CAR Level Pot full CW
9. Flip to Send
10. Check TIF level at TP-2
11. Check level at MD (if level is low try adjusting the Drive Control to peak the reading)

and Drive fully CCW I get:
TIF at TP2 810mv meter set to 1.5, -DC
MD 1.5v meter set to 5, -DC

7.200 I get the followoing
TP2 TIF, 800mv
MD 1.2v

probe test at IF board.
VFO 250mv

Other radio settings.
load 1200
Car fully CW
Dummy load.

Thanks
Carlos

Peter
Similar to the other comments, I have used both amplified and unamplified D104s (two distinct devices) with my TS830 and they both work fine. On air reports don't show a significant difference. As a back-up, I made a small adaptor cable so I could adapt from the 4-pin KW plug to the Heathkit style plug for my HW12. One thing I have noticed, being sloppy with the wiring may introduce hum. Always be sure to have the mic wire as the one in a separate shield. There is always enough time to do the job over, but never enough time to do it right the first time.

Topic: 52960 Message: 52960

Guys,

I was looking through a few old mags the other day and came across this:

INCREASED SENSITIVITY
On the RF board, Q5 is the RF RX amp
G2 is tied to the AGC line - bend G2 up from the socket, solder a 10K resistor to it and connect the other side of the resistor to the 9V line on the front of the board. This will allow the FET to run wide open and improve S/N ratio. This should give you 2 S points more signal.

Has anyone heard of or tried this? It sounds a bit like this is partially disabling the AGC, what do you think?

Cheers,
Peter - VK2AN

"...This should give you 2 S points more signal..."

Someone is confused what _the "signal-to-noise"_ engineering term means.
I doesn't mean an _increase in amplitude._
That's stupid.

Carlos:

NO GOOD.

Are you using a 10X probe?

CAR osc will be approx 2.45 P-P volts or 870 mv rms

Het osc will be approx 4.0 P-P volts or 1.4 rms volts

VFO will be approx 2.4 P-P volts or 835rms volts

Put the O-scope away for now.

Carlos:

Seeing 810mv of TIF signal at TP-2 at 14.2 mhz tells me that the Drive Control is not properly adjusted for that frequency. Should never have the Drive Control at full CCW at 14.2mhz. It means that the LC circuit in the Drain of Transmit Mixer Q3 is not tuned to resonance.

While watching this 810mv rf drive level at TP-2 can you adjust the Drive Control for a null or lowest voltage reading on your IM-18? It should null around 100mv or the 1 on the 1.5v meter range.

If you can null the RF voltage leave the Drive Control at that position and then move RF probe to MD and see what reading you have. If you still have approx 1.5vdc on the 5 volt scale that is good. It means you have adequate TIF signal and the TX Mixer is working. Now need to see if the Driver tube is working.

Now you have two choices of where to measure next.

1. At DRV or DP. This is the Plate of the Driver tube and you have to be careful as in addition to the RF drive voltage there will be over 300 vdc at this point and you can get a nasty shock if you make contact with the test point. Your PK3 has a dc blocking cap in it so it can read the RF drive here without being damaged.
It may take a few seconds for the reading to climb up and settle out. Just as soon as it settles flip back to Stand by to let the Driver tube cool off.

It may be easier for you to read off the Frame (stationary plates) of air variable capacitor VC-3 which is the one closest to the PA cage. Less chance for your RF probe tip to slip off here.

2. Your second choice is to move directly to the Control grids of the Final tubes at Pin 5 of the octal tube socket and measure the RF voltage there. It should be at least 39 volts.

Report back DRV and Control grid RF voltage levels.

Having the Plate Load capacitor at 1200 is not necessary. The Plate Load and Plate Tune capacitor positions mean nothing in this test as you have the Screen grid turned off and you are not producing any RF so Pi network is not involved and the position of either capacitor makes no difference in the RF voltage you will read.

Lastly at this point if you have 1.5 rf volts at MD then you have to have the ALC bus energized so dont worry about measuring it at AGL on the IF board on at ALC on the RF board.

Carlos:

I forgot to mention that the PK-3 probe when built had the option of installing 3 diodes or one diode and two jumpers on the PC board. I would think that most builders would have installed all 3 diodes, but you may want to check to be certain.

To do that remove the two small screws from the black plastic cable feed thru piece at rear of the probe. Pull the black plastic piece from the aluminum tube and slide it back along the coax and braided ground cable. Using a brite flashlite look inside at the PC board and you should be able to see the 3 diodes in a row.

If only 1 diode is installed you cant use the PK-3 for measuring DRV or 6146 control grids. Hopefully I am not too late with this note.

If there is only one diode you can easily disassemble the probe and remove the small PC board and install 3 germanium signal diodes. IN34A or IN270 will work fine. Can use Schottky diodes as well, but will increase the lower rf voltage levels that you will be able to read. It is a good idea to have a 1 diode probe for small signal work like TIF signal and a 3 diode probe for Driver tube plate and 6146 control grid measurements. Just have to ensure that both probes are clearly marked as to being 1 diode and 3 diode probes.

The Heath 309C is a one diode probe.

Carlos:

OK good that it is a 3 diode probe. OK to use it at Plate of 12BY7A tube (DRV and DP) and the control grids of the 6146 final tubes.

I meant to get on the solder lug of the Small Plates of VC-3 which is the lug closest to the PA cage. You should see approx 60 volts there.

No you dont want to adjust Drive Control for a maximum of 780mv TIF signal at TP-2 if that is what you did. That means at 14.2 mhz the Drive Control is not at approx 1200.

You want to adjust TIF for the lowest millivolt reading you can get or a null and not a peak using the Drive control. With the Drive Control adjusted for a null at TP-2 using a 3 diode probe you should see something around 100mv or less. The TIF signal is actually higher than this because each diode has a barrier voltage or turn on voltage. So the TIF signal level must be high enough to overcome this voltage and the indicated voltage will be 100mv or so lower than actual rf drive voltage at TP-2.

It may be easier for you to move the probe to MD and adjust the Drive Control for a null or lowest RF voltage. Probably around -1.8vdc on the IM-18 5 volt range.

Are you trying to touch the probe tip to the top of the MD wire wrap post? If so it is very easy to slip off. See my website photos for how to make an adapter to get on these post. You can use a short alligator test lead and clip on MD and clip to the probe tip. However, the higher you go in frequency to run the Level Diagram the lead wire can de-tune the LC circuits and influence your readings. I wouldnt try to take rf voltage higher than 14.2mhz using clip leads. If have trouble at 14.2mhz using jumper leads to connect your PK-3 then go to 7.2 mhz to measure the rf drive voltages.

If you have 1.5 to 2 volts of RF drive at MD with the Drive Control close to 1200 position it means that the TX Mixer is seeing the required TIF input level, required HET LO input, the required band switch selected LC circuit (Mixer coil), required DC voltages for the mosfet to function, and of course a good mosfet device.

Now you are telling me that you have no rf voltage at solder lug S on VC-3 and no voltage at DP or DRV and of course there would be no voltage at Pin 5 of the 6146 final tubes if you have no DRV signal. Ask yourself why could this be? If what you report about MD is accurate then you have just used the TX Level Diagram to isolate the problem to a stage in the RF output development ie the Driver Stage.

What are some of the possible causes?

1. Bad Driver Tube (very low emission or an open filament can you see it glowing?)
2. No Plate voltage on the Driver tube
3. No Screen grid voltage on the Driver tube
4. No switching from cutoff to operating bias on control grid Pin 2 of Driver tube
4. An open C3 100pf capacitor (kind of rare)

5. Bad solder connections at the Driver tube socket

Best to use a Pomona Test socket to take Driver tube voltages, but lacking that tool if careful you can take the operating dc voltages with the tube in its socket. I would remove the tube shield to do this. If you have trouble you can remove the tube and take the dc voltages.

I think you are making progress just be ever mindful of the 900vdc and the 300vdc locations and dont make accidental hand contact or swing test leads into it.

Carlos:

One more thought.

If you are telling me that you are seeing approx 800mv of TIF signal at TP-2 when peaking the Drive Control around 1200 at 14.2mhz or 7.2mhz then it is possible that the Drain of Transmit Mixer (Q3 Het Mixer) is not seeing the impedance that the Driver tube normally presents to it. When this happens there is no load on the Transmit Mixer and the TIF signal will go quite a bit higher than normal. Normal would be around 200mv.

I am still not clear in my mind if the 780mv TIF that you report is with the Drive control peaked around the 1200 position both on 14.2 mhz and 7.2 mhz. Or if that is with the Drive control full CCW or full CW. If it is the latter you are not using the Drive Control properly and need to null the measured rf voltage around 1200 and see if you have approx 100mv signal. I say null as ordinarily you would peak it using the ALC meter indication, but since you dont have that indication you need to null the IM-18 voltage indication and that null should occur close to 1200 on the Drive Control.

There are essentially two loads presented to Q3. 1. The bandswitch selected LC mixer tuned circuit. 2. The essentially conductance load that the 12BY7A control grid presents due to the capacitive reactance of the inter-electrode capacitance from control grid to cathode.

The load to the Transmit Mixer can be missing if there is a bad bandswitch contact which is unusual on a TS520 and usually not all bandswitch positions are bad and/or the control grid of the 12BY7A isnt being seen due to bad inter stage coupling capacitor C21 (very rare) or bad solder connection at the 12BY7A Driver tube socket (much more common).

1. Did you try another Driver tube?
2. Try gently pressing down and rocking the Driver tube around in its socket.

What I am trying to tell you is there are two conditions you can encounter when running the TX Level Diagrams. 1. Low or missing rf voltage at the test points OR 2. Abnormally high rf voltage at the test points. Abnormally high can be due to not properly adjusting the Drive Control or missing loads.

Summary:

Measure TP-2 and adjust the Drive control for lowest voltage indication on 1.5vdc range. It should be close to 100mv with Drive Control close to 1200.

From: carlos@...
Topic: 52917 Message: 52973

Terry,
The 780mv was as low as I could get it.

2.5V at the lug close to the PA is the best I can do. At 1200
640mv at 1200 on TP2 is lowest as I tried to get lowest possible.
Lowest possible on MD is 900mv with the knob fully CCW. High is 3.5v at full CW. 1.8mv at around 1200.
I am using a jumper cable, I get about the same on 7 and 14 .

On VC3 I am measuring at the lug on top of the VC. No voltage on the one away from the cage.

DP I am measuring at the DP post by the cage, same with DRV.
DP = 680mv
DRV = 2.4v

disregard pin 5 at the socket, I was measuring at the drive tube.

Drive tube, I do see it glowing at the top, this is a NOS tube.

As for the HV, I have one hit already, don't want another. So power down, clip, power up, test.

Pomona test socket?

So with the above rechecks, proceed with the 5 possible issues you mentioned to test?

Thank
Carlos

Carlos:

There are some confusing items in this report.

1. I think you are saying that the lowest null in the rf voltage measured at TP-2 (TIF signal) is 780mv. Then you say you were able to null it to 640mv with Drive Control at 1200 position. If that is true then the lowest TIF signal at TP-2 is 640mv which is of course high by about 3x normal which means that Q3 TX Mixer isnt seeing the Driver tube. Since we were looking for approx 100mv we wont quibble about 640 to 780mv.

2. You say you got 1.8mv at MD with Drive control at 1200. Do you mean 1.8 volts?

3. You say that you get 680mv at DP and 2.4 volts at DRV. This doesnt equate as they should both be the same rf voltage as both our the same point electrically. Regardless either rf drive level is extremely low when you should see approx 60 volts.

As noted if TIF at TP-2 is 640mv to 780mv it would seem Q3 is not seeing the Driver tube. Also if you do have 1.8 volts to 3.5 volts at MD and only 2.4 volts at DRV then the Driver tube isnt amplifying the RF drive.

RF drive at MD is coupled by C21 150pf inter-stage coupling cap to the control grid Pin 2 of the Driver tube. I have never seen a bad C21 but certainly possible.

Before we start suspecting bad coupling caps I think you should pull the Driver tube and measure the voltage at 3 of the tube socket pins in RX mode and in TX mode (flipped to Send).

Looking down on the tube socket from top the 1st pin CCW from the notch in the socket is Pin 1. The pins are numbered from 1 to 9 going CCW. Measure the following DC voltages with your IM-18.

Pin 2 is the Control grid. It should have negative -36vdc cutoff bias on it in Rx mode and +0.36vdc operating bias in Tx mode.

Pin 7 is the Plate and it should have + 325vdc in Rx and TX modes.

Pin 8 is the Screen grid and it should have + 236vdc in Rx and Tx modes.

With tube in the socket and under load the SG and Plate voltage will be lower but we just want to make sure it is there in Rx and Tx modes at this point.

The above 12BY7A driver tube voltages are approximate levels.

Report back these three voltages. I understand you installed an NOS 12BY7A tube. It may or may not be any good.

This subject was covered on this forum back in July 2011 I believe.

You can find the discussions by searching on Conversations. I know that I and W5RKL and others discussed this when Dan KI4AX brought it up.

To apply 9vdc to the control gate of the RF amp dual gate mosfet is silliness. If you look at the mosfet characteristic curves you will see that the knee of the gain curve occurs at around 4vdc to 5vdc volts applied to Gate 2. There will be no gain increase after that level of dc control voltage. Normal control voltage supplied by the AGC bus is approx 3.2vdc with no off air signal.

KW selected that level for optimum signal to noise ratio.

If you want to improve weak signal copy on the TS520 10/15/20 meters then employ a high gain directive antenna and/or a pre-amp.

There are many mods out there that have no testing to support the claims.

With the TS520S KW added an automatic capacitive voltage divider shunt attenuator circuit. They reduce the signal level applied to the RIF Mixer on the low bands by shunting some of the signal from the RF amp mosfet to ground and they switch the attenuator out on 10 meters and run full gain. This helps especially on 160 where strong local AM could cause 2 signal intermod. The 820, 530, and 830 have similar RF attenuator circuits.

You can see a description on page 11 of the TS520S service manual. This feature and several other important changes were made from the TS520 to the 520S models. If I were to own only one of the two radios it would be a 520S. It is the better design.

Carlos

You can see that you have cutoff bias switching to operating bias. You have screen grid voltage, but no plate voltage assuming that you were making proper contact with your Fluke. If no plate voltage that is a bad thing as can exceed the Screen Grid dissipation and destroy the tube. Hopefully that hasnt happened.

What is the next place you should have checked when you saw no Plate voltage?

Why didnt you go to wire wrap terminal 300 next to L6 to see if you had plate supply voltage to the RF board for the 12BY7A tube? If you dont have approx 330vdc there then you need to go back to the HV rectifier board and see if you have it there. If not there then you need to look at the 300 supply filter caps and the 470 ohm series resistor in this CRC Pi-filter.

I have no idea why you would be measuring at TP-1? Q4 is the RIF mixer. TP-1 is provided as a point to inject RF from a Sweep Generator into Q4 to perform receiver Band Pass Filter alignment. We arent interested in that. We can talk about your thought process off List.

We need to focus on troubleshooting NO ALC indication and NO RF Output.

At this point we can take this off the Forum as those who were following along trying to run the TX Level Diagrams on their own 520s now can see how it led us to the Driver stage as the problem. I would also remove the NOS driver tube from its socket until you have restored the 300 supply to the RF board. It may not have been hurt yet.

Lastly, if you find 330vdc at the 300 wire wrap post on the RF board then we will need to follow the path to the plate of the 12BY7A tube. There is a Plate choke L6 next to the post that sometimes burns open. It is a green can and sometimes the top half of it turns dark brown or dark black. There is also an L6 choke in the path on the Drive coil hanging board and the plate voltage is supplied thru the 80 meter Drive coil L1 on the hanging board. Most common failure would be back at the HV rectifier board and the 300 filter bank. Bad diode, bad filter cap, bad CRC 470 ohm resistor.

Carlos: Please reply to this response off List via email.

Those who contacted me off List during this long back and forth with TX Level Diagram questions I will continue to provide you with whatever help I can off List. I did answer some of your questions on my website under the FAQ section where I discuss some of the TS520 TX Level Diagram items that may be a bit confusing.

Topic: 52978 Message: 52978

I have the accessory kenwood cw filter for my TS 520. This is what I am experiencing.

I successfully installed the mod that allows me to cut the cw filter on and off via the crystal switch. When I engage the filter, it does filter. It seems toe attunate the signal and I am hearing weird noises/signals in the background of the intended signal. I can hear other cw signals that are not there with the filter disengaged.Its like it is pulling signals from another frequency and they are in the back ground. I am running 10 watts to a johnson thunderbolt amplifier. With the filter off, I get 10 watts out which is what it is suppose to be. When I engage the filter, it cuts my wattage back to 5 watts.

Any idea what may be going on? Thank you brian kb4mng

Topic: 52960 Message: 52980

Terry,

Thanks for the great explanation. I suspected it was a waste of time, but i just wondered if anyone had come across it before.

Brian,

Actually my TS520S is remarkably sensitive, I have done comparisons between the TS520S, a TS940 and an IC7600 using a sig generator and I found the TS to be almost the same as the 940. The IC7600 was slightly better with the pre-amp on 2, but worse with it off which was quite surprising.

It seems that apart from the bells and whistles, we haven't really come that far since 1978....

Please note that this was only a straight out test of sensitivity - third order intercepts and other such tests may be a different kettle of fish.

Cheers,
Peter VK2AN

Hi:

There is a published mod to convert positions 3 and 4 on the fixed frequency switch to control a pair of filters as well as the mod to insert an additional switch. That would be a really "sanitary" way to add switching filters and making it look 'factory'. You could also put a toggle on the back panel or bottom of the radio.

I'm attaching a copy of the mod I found and I believe it is contained in the set of popular mods which are floating around out there.

TS-520, TS-820 CW filter select control

In the TS-520SE, the heater switch has been replaced with a CW WIDE/NARROW select switch. For those operators who desire this type feture for their transceiver, the following information may be considered as a guideline.

TS-520S series transceivers
A minature SPDT switch may be installed at the operators preference, on the rear side, or bottom panel. Use this to switch the CW or SSB filters by wiring the BROWN lead, which normally is transferred to the CW terminal on the IF unit, between the SSB filter, for WIDE , and CW for NARROW. A Traditional solution has been to use the FIX CH switch, position 3 and 4 for filter switching. This may be donw by completely rewireing the switch, or by leaving the switch wiring and the filter wiring as for normal operation, and bridging the following terminals:

A. FIX CH C terminal to IF SSB Terminal
B. FIX CH 4 terminal to IF CW terminal
Placing the FIX CH switch to 4 will operate the SSB filter
in CW mode.

TS-820S Series Transceivers
Similar to the TS-520 series, a miniature SPDT toggle switch may be installed at the

operators preference a the rear or on the obttom cover. The FIX CH switch, or Digital Hold switch may be rewired to control the CW wide/narrow function
On the MODE switch, S6-1, the SSB filter control is GREEN, and the CW filter control line is GREY. Break the GREY line and connect it from the MODE switch to the SPDT common terminal. Connect the GREY line to the IF unit ot one terminal, and bridge tht GREEN SSB line to the other Switch terminal.

Topic: 52978 Message: 52983

The mod on Mods.dk and other places looks incorrect. I'm thinking the correct way to install the mod with using the Fixed switches would be to remove and extend the wire normally on the SSB test point to the "C" test point on the Fixed Crystal Bd. Then run a wire from the SSB TP to the Ch.3 TP and a wire from the CW TP to the Ch.4 TP on the Fixed Crystal Bd. So Ch.3 would be the NORMAL audio and Ch.4 would be the switched-in CW filter. The author mentions the Ch.3 switch but never says what to do with it.

The way the mod is written it would normally be the SSB filter but the Ch.4 position on the switch would be BOTH the SSB and CW filters at the same time because you never break the SSB connection the way it's written. Is my interpretation correct? My way it's the same as adding an new SPDT

The reason I asked about the filter switching is because I "won" a CW filter last night on ebay for my 520S and won't be able to install it until next month. I like the ability to listen to the CW filter in and out of the circuit. It "may" also be why you are hearing weird stuff if you wired it the way the mod written.

Hi Folks;

I have heard of the same mod. It is on the DK Mods site: http://www.mods.dk
http://www.mods.dk

I know nothing about it. I had asked the group about this mod a while back but "ain't heard nothin' from nobody". Thought maybe I'd get a comment from Terry, who seems to be a very astute gentleman.

I've studied my TS-520 (not an "S") schematic and the AGC controls the first RF amp (which is what this mod is about) and the IF amps. The RF GAIN control appears to take hold of the AGC line and uses it to turn down the gain on the same amps on the same way.

A friend of mine told me the following in an email. He is very knowledgeable about radio design and does work for governments:

" Generally speaking, to get best dynamic range it is necessary to run the RF transistor at fairly high current levels so in can't overload on the strongest signals. Especially military grade sets where multiple stations will be running in close proximity.

Some broadband pre-amps actually use a power output device running at 5 watts or so.

So if you simply reduce the bias it probably will reduce the dynamic range. But it's impossible to give a blanket answer. It depends on how clever the designer was."

So I asked the group what they thought of this mod, because it would appear to follow the general case recommendation that I just quoted, as far as I can understand it.

Rather than have the TS-520 AGC and RF GAIN control turn down the first RF amp along with the IFs, I wonder if the TS-520 could be improved by letting the first RF amp run "wide open" as the mod says.

I am not after better sensitivity, since I rarely go above 20M. My particular TS-520 (not sure if they all behave the same) sounds much better with quite a bit of attenuation ahead of the receiver (which I added in myself by "borrowing" the WWV/JJY switch for that function).

My understanding is that the TS-520 has a tremendous amount of RF amplification which is the sum total of all the stages. Perhaps too much for the high QRN and (crowded) signal levels typical of the lower bands.

My TS-520 is very susceptible to IMD on 80M when signals on the band are very strong. I can easily hear fragments of CW fleetingly when in the CW portion.

On 40M is just sounds so much better with 20-30 dB of FE attenuation when signals are strong at night.

Sure, this messes up the S-Meter readings, but those are relative anyway. S-meters don't measure anything, except for the vicinity of S9 if they were calibrated accurately. The S-meter on the TS-520 is giving an indication of how the AGC voltage is varying with signal strength. My understanding is that it is cheap and easy for manufacturers to provide an S-meter in this way.

I'm no engineer; I've gotten this far with my quest to improve the receiver section. Any additional technical comments would be greatly appreciated.

Thank you,

Garry WA1GWH

Hello Ed,

This is Walter Dilley, kd7dny. I recently purchased the Hybrid Parts Inventory from Bob Mansker. Bob used to supply parts to us but has exited the business and bought an RV so he could "go fishing with the grand kids." I now have it all in a large pile of boxes in my living room! I may have a VFO dial and knob but need more specifics such as model #. If you could send a picture with pointers to which part you need, I can look for it. If there is anyone else on the list that has one, they could look, too. What

happened to the old one?

Do you have a callsign, Ed?

Thanks,
Walter, kd7dny

Brian

Have you tried adjusting TC-1 trimmer cap on the Carrier Oscillator board in CW Tx mode for maximum RF output? Some use a freq counter and set the oscillator to exactly 3.395. The filter Fc may not be spot on. Best to bring the oscillator to the filter.

Terry,
I have to agree with Kevin. This is the purpose of the group in the first place. What rationale was used to make the comment that this be taken "off list" where only 1 person benefits from your sharing of knowledge? That makes no sense. I'd have to ask the person(s) who asked that it be taken off list what, then, exactly, is the reason FOR the group? We all have a lot to learn, and that is hindered by those asking for a very informative topic to be taken "off list"
Kevin, it would be nice if you shared that word document, and maybe have Terry, and Mike, and others add to it to build a "book of knowledge" in addition to the schematics and manual. 73

As Lou Holtz famous ND football coach once stated "I am just the Monkey on the end of the chain. You will have to ask the Organ Grinder"!

Not the first time I have been asked to take technical topic off the List. This didnt come from the owner. I have bumped heads here in the past and you are looking at the new and improved Terry. I am getting too old to push back very hard anymore.

With thousands of members not possible to make everyone happy. I did agree with the individual who made the request that the thread can get long when trying to teach basic electronics, troubleshooting methods, how to use test equipment and KW hybrid model specific circuits and test points etc. Couple that with "I said and he heard" difficulties and some repetition and frustration protracts the thread.

Here is where it stands. TX Level Diagram measurements revealed that there was no RF voltage at the Anode of the 12BY7A tube at DRV test point (should be approx 60 volts). Carlos then found no 300 supply voltage to the RF board. He went back to the HV rectifier board and found that there was no 300A supply voltage. He found that CRC Pi-Filter 470 ohm resistor R5 had gone infinite. Right now no determination as to the root cause. C15 and C16 dual can 22uf filter caps are new so not likely the cause. R5 is carbon composition and hygroscopic so it may just be age related. He didnt have a 470 resistor and had to order one. As soon as he gets it installed he will confirm that he has anode voltage at the 12BY7A Driver tube and will try to load the radio. I have asked him if he gets good ALC indication in Tune mode to repeat measure the TX Level Diagram RF voltages at TIF, MD, DRV and the control grids of the 6146 final tubes and record them for future use and to report his findings back on the List for closure for those who were following the thread with interest.

Anyone who has questions about any of the TX Level Diagrams can contact me off List for help. It takes some experience to learn the test points, understand instrument effect on readings, what abnormal low and abnormal high readings mean, and there are errors on the diagrams. Still a very useful tool that KW has provided us.

52996. ALC problem with CW filter?

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-09-09 22:02:35 UTC
From: lopez@...
Topic: 52996 Message: 52996

Hello friends.
I made my TS820S modification CW filter with the DH switch on the front panel, so that I can receive CW filter without the filter, but today I noticed that in TX, when not use the filter, ALC indication have, with in CAR in position 4, and when I connect the filter to that the ALC have indicated, I have to put the CAR to the fullest, and yet, only 50% of the scale is indicated.
I can not say if before the modification as was the case, since I had never noticed.
This is normal behavior ?.
Best regards from Spain.
Rafa. EA5TV

To those following .

In short and I will post a more detail follow up. Filter board was the problem. 300v AC was OK, 300vdc after diode was ok. 300v after R5 470ohm 2W was missing. Bad resistor right, worng, smoked it after replaced, checked continuity between ground and wire wrap post 300A and I had continuity. 2 wires are on that post, one to the drive socket and one to filter cap.

When I replaced the caps I had pinched the purple going to the drive socket, direct short. Not finished yet. I have made two contacts, one to Aruba P40ET and one to WV6VAH

Kevin, ditto what you said.

Thanks
Carlos

Carlos: Thanks for the report to help close the thread. One correction. You dont mean the "filter board". R5 CRC resistor is on the Rectifier Unit board. It is the series resistor in the 300 supply filter. A resistor is used in lieu of a choke as it is a lower cost alternative.

One of the lessons learned is that any time a radio stops functioning or has a new problem after we have worked on it the very first thing we should suspect and re-inspect is the work that we just performed. Even if we are an attention to detail person and believe we did careful work and inspected the work in progress we need to suspect what we did and carefully review it again.

It is the goal of all corrective maintenance (CM) to fix the problem and restore the radio to design operation. It is the goal of preventive maintenance (PM) to extend the life and reliability of the radio. It is very easy during CM or PM to damage something obvious or to induce a fault that will manifest itself immediately or be a latent fault that will come back to haunt us commonly as an intermittent down the road.

Sometimes on 30 to 40 year old radios of any kind it is best not to fix things that are not broken. KW hybrids have at least three weak links. Molex connector pin soldering, molex pin lead wire crimps, and poor quality phenolic PC boards.

Total recap of a KW hybrid is one of those tasks that must be undertaken understanding the risk vs reward which I have spoken about numerous times.
You would think intuitively that it is a good idea to replace all of the aluminum electrolytic capacitors, but fact is they dont all degrade at a log rate over time and receiver and transmitter performance seldom declines at a perceptible or measurable level. The results you obtain is often "feel good" results. I ESR all removed caps and often find them to be well within spec.

Here are some of the risks involved in total recap:
1. Pull molex connectors off the PC boards.
2. Break solder at individual molex pins.
3. Break the crimp connection on end of wires in molex connector plug body.
4. Introduce hair line cracks at the molex pin pad to trace junction that are near impossible to see due to the solder mask coating. A source of intermittent operation that isnt easy to troubleshoot.
5. Lifted PC pads and foil traces. Most common problem. This requires installation of jumper wires and dragging solder across cracked foils.
6. Installing caps reverse polarity (positive to ground instead of negative to ground)
7. Installing caps that need to be reversed polarity wrong (positive is not to ground and is required to be in several locations). This one is a challenge as often the schematic and/or silk screening is wrong and the as built config is correct assuming someone hasnt changed cap before your ownership.

I do not perform or sell total recap service. I do recommend replacing high energy caps like the 900vdc and the 300/210 caps. These caps especially the 900vdc have a history of

swollen and cracked rupture vents and failure of at least one of the two and when they fail can cause collateral damage.

Of course it is your radio and you can recap if you want. Using the same logic why not replace all carbon composition resistors? Never hear anyone promoting this. There are many resistors that go high and even infinite over time. Regards resistors I replace those that commonly fail such as CRC filter resistors, cathode meter shunt resistors, screen grid stoppers, screen grid voltage dividers etc.

Carlos, again thanks for the closure. If you discover other operational issues with your radio that were not there before the total recap you will need to inspect your work and that may not be an easy task.

Hi Joe…

Because it has run on every one of my ham related groups. This time from a ‘Wolfe” (Not related to me) Previously, by someone else KJ6DBP (Norma Grimes, in southern Cal). I have emailed them and received no replies confirming ownership of said equipment. In my groups, ***IF*** they are members, I send an email telling them they have been deleted due to spam and to re-apply with a different email address. In some cases, they aren’t even in my group yet still posted the ‘for sale’ post. Hard to stop that one.

Today, this was in the APRS group that I am a member:

Quote:

KC0FTN
RICHARD W WOLFE
Email: KC0FTN@...

End Quote:

From a month ago on another APRS based group

Quote:

From: APRS_Radio_Built-in_TNC@yahoogroups.com
[mailto:APRS_Radio_Built-in_TNC@yahoogroups.com]
Subject: [APRS_Radio_Built-in_TNC] Forsale: Icom IC 7800 & ICOM IC 756 PRO 3 with ICOM PS 125.

Forsale: Icom IC 7800 & ICOM IC 756 PRO 3 with ICOM PS 125.

Callsign: KJ6DBP
Email: kj6dbp@...

Yaesu FTdx5000MP
It includes the SM-5000 station monitor, the temperature controlled oscillator for 0.05ppm freq. stability and the 300Hz roofing filter all factory installed.
This radio is in excellent condition. I do not smoke, the latest firmware is installed.
The radio comes with a mic but does come with the FH-2 keypad, owner's manual and the various power and connection cables required.
price: $3,050

End Quote:

And this again, in *my* group, HeathKit_HFAmps, using yet another name and call:

Quote:

From: kf4zci.herbert@...

Forsale: Icom IC7800 & ICOM IC 756 Pro 3 with ICOM PS 125

End Quote:

But signing it as Norma Grimes, KJ6DBP

Note they are all high dollar radios, and all have the same mis-formating of the For Sale information. I forget on which group, but someone did a trace back on one of the originating posts and found it came for some Slovic country.

Perhaps to put your mind at ease, you could email the seller and asking him/her to clarify their sale items, and perhaps send up some images with the call dign displayed in the lcd read out, which all of those radios can do.

73!

Greetings group,
After careful consideration of the info provided by group members, the person concerned has been banned from the group, and the add/msg removed from the group's archive.
I understand that the person whose call is used, may not even be the perpetrator and unaware, but the goal of the group's administration is to keep the group as free of spammers, scammers, and hackers, etc. as possible. It was my fault that this add got through. The person was a very new member...9 days, but the add conformed to the group's policy on items for sale, and thus, was approved. I will ponder possible changes in the group's "for sale" policy. Any comments and REASONABLE suggestions will be considered..just send them to me "off-list" or to "group owner"

Again, TNX for helping keep the group clean!
 73

All,

Isn't it best to just ignore them? Same as on repeaters in the old days when folks tried to jam with carriers and such? They usually go away.....Besides, if they are legit, they wouldn't be here in the first place, they'd be where they might find buyers for their overpriced stuff, geez, the prices are outrageous...I'd never pay them...I had a tough enough time finding the money for my 530...wow.

Hello fellow Hybridites.

I purchased a Heathkit SB-200 today at a hamfest. I'm researching the connections for the ALC and the Relay.

For my TS-520S, I found the info doing a search here and confirmed it in the TS-520S manual.

For my TS-830S, the Remote Connector pin-out is different and shows ground on pin 8 according to the schematic in the user manual. The diagram on page 8 doesn't even show pin 8. On the rear Remote Connector I'm pretty sure the center conductor of my ALC is on Pin 6 and the Relay (normally open) is on pin 4. Is pin 8 the ground for both? Help?

Ron, you should check the ALC threshold voltage of the SB200 before you
do anything.
I would not advise using ALC with either the 520 or 830.

Hi everyone. I just came into a TS-530S (and some accessory components) and she's beautiful. I'm still learning my way around and know from experience that being a contributing member of a group like this can be very helpful.

I hope I can bring something to the group.

53026. Kenwood Hybrid Net Update (September 13, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-09-13 21:52:59 UTC
From: Mark Gilger
Topic: 53026 Message: 53026

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by me, WB0IQK. There
were 27 stations checking in under good band conditions.

We had the following number of radios checking in.

3 running TS-520(x)
3 running TS-530(x)
1 running TS-820(x)
4 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running a Drake TR-7 with my L-4B AMP.

There was no Sunday net this week. Both Jimmy and
myself were attending local hamfest.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit

and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total = 142, Sunday☐s total = 88
December 2014, Saturday☐s net total = 92, Sunday☐s total = 86
January 2015, Saturday☐s net total = 110, Sunday☐s total = 84
February 2015, Saturday☐s net total = 103, Sunday☐s total = 98
March 2015, Saturday☐s net total =80, Sunday☐s total = 51
April 2015, Saturday☐s net total = 59, Sunday☐s total = 29
May 2015, Saturday☐s net total = 79, Sunday☐s total = 48
June 2015, Saturday☐s net total = 70, Sunday☐s total = 38
July 2015, Saturday☐s net total = 26, Sundays☐ total = 56
August 2015, Saturday☐s net total = 73, Sundays☐ total = 65
September 2015, Saturday☐s net total =45, Sunday☐s total = 6 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:

Kev,
First get the manual here: http://www.n6wk.com/kenwood/VFO-240%20Instruction%20Manual.pdf
It's free of charge.
You will of course need the interconnection cable.
 Looking at the front upper right of the VFO-240 you will see 4 position selector switch labeled: RMT - R
MAIN RMT MAIN - R
RMT - R: reception frequency is controlled by the remote VFO transmission frequency is controlled by the main radio VFO
MAIN: reception and transmission frequencies are controlled by the main radio VFO
RMT: reception and transmission frequencies are controlled by the remote VFO
MAIN - R: reception frequency is controlled by the main radio VFO
transmission frequency is controlled by the remote VFO
   Selection of what does what is automatic and depends on what position the selector switch is in. Obtain manual, read it, and try out the functions...it is rather intuitive once you've done it a couple of times..
Cheers.....

Hi Joanna..

Perhaps in your ire, you put your post in the Subject line! J

Manuals are always good to have read. But many times, the manuals are hard to understand. I even encourage folks to search the message archives, but with this new way of doing things in Yahooey, it is not all that easy a task.

So, In my groups, (This is *not* one of them, the 'other Joe holds that title!) I just let the questions come and many times, those answering will also reference the page in the manual, where the answer can be found. That accomplishes 2 things, The question is answered and the OP learns how to read his manual.

Patience ma' dear. Sometimes we forget how 'complicated' these older radios can be, to a newbie. J

Joe - W7RKN

of any kind.

The group's policies message can be download from Yahoo KW
TS_520_820_530_830 group file section in the AUTOTEXT MSGS folder and
file link "Message on approved membership.txt". You can also download
the same file from my website (click on the following link):

http://w5rkl.com/wp-content/uploads/2015/02/Message-on-approved-membership.pdf

The file, in the above link, is the same file except the "page #" have
been removed and the file was saved in pdf format making it easier to
load and read. Simply click on the link and the file will download to
your computer and once download completes, it should automatically
launch your pdf reader and display the 4 page file. This is assuming you
have set a pdf reader such as Adobe reader as the appropriate software
package for reading pdf files.

Joanna,

That is now how things are done today, Joanna. Reading the manual first would take some effort and work by the owner of the equipment. The order of the day is to buy older equipment, never knowing how it works, not trying to know how it works, have no test equipment or knowledge on how to use it and have no interest in having parts on hand. How many times have you seen, "Hey gang, anyone have a 100 ohm 1/2 watt resistor, I need one? How many times have you read, "My radio is broke, got any suggestions"? Then 1000 messages trying to "shot gun" the malady. No science used or offered as a clue to what is wrong with the apparatus. Get used to it Joanna, this is 2015.
Lee, w0vt

Is this just a group of old grumpy folks? I see people complaining about every little thing.

To top it off, there's no 'private conversation' going on here: user A asked for info, user B provided it, user A verified that it worked and thanked user B. Embedded within these messages were instructions about how the pieces worked together as well as some gentle prodding from other users (and user B) about reading the manual.

It seems to me that the purpose of the group is to provide support to people who don't understand their radio. Some of those questions are going to be very simple. Some of those questions are answered in the manual(s). Some of them are answered (ad infinitum) in the group already - but good luck finding those as the search function is nigh unto useless. If you don't want to help, then stop reading. That's a lot simpler than complaining about every little thing that gets your goat.

The flip side is that, if you want these radios to keep working you're going to have to expend some effort. There's no doubt that some of the posters haven't done their due diligence. There's no doubt that some of them don't have a single diagnostic bone in their body. There's no doubt that some of them don't even have a multi-meter. But, you know what? If they don't get pointed in the right direction they'll toss their radios in the closet and that will be last they're seen until <SK>.

The operator and service manuals contains valuable information for both operating and servicing of the Kenwood hybrids. Quite often problems can be solved by referring to the operator and service manuals.

This group is here to help but you also must do your part as well. This means you should spend time studying the operator and/or service manuals so you have a better understanding of how the KW hybrid works, how to properly operate the radio, what the controls are for and how to use them. You should also study the Circuit Description section and block diagram so you will be better prepared and possible find the source of your problem(s). Servicing your KW hybrid without the manuals, knowledge, and skills, will be very difficult for you.

Again, any message you post on this group must have an acceptable message signature added to the end of your messages.

Greetings group,
Enough is enough already. A member asked some questions, I answered them. Could the asker have found the answer another way, sure, but chose to post it to the group, isn't that why this group is here? I don't think he'll make that mistake again. I was not having a personal chat on the group board. I was answering a question and giving direction on the group board and it was available for ALL to see, no matter how trivial or beneath you, you may have thought it was...it's called a GROUP BOARD for a reason. Have I wondered why someone just doesn't "read the manual,"....YES...have I gotten irritated that I seem to be able to do it...why not you?.....YES, but I must balance remarks, statements and decisions on the group's mission and policies. Some people make accusations easily...but if for some reason you thought I was having a personal chat on group time, you should have sent ME a personal msg or just ignored it.
That being said, take a deep breath and get over it. If you do not like the way the group operates, what members can say(within the rules), either deal with it or, feel free to "unsubscribe," you may live longer. If you have something to say about how the group is run, send it to "group owner," or me personally, I'll get both.
I apologize to our members on the other side of the pond.
Cheers.....

I also as a newbie find the discussions here very useful. I am very mechanically inclined but when it comes to to reading electrical the diagrams, and such, I can follow the circuit diagrams, but yet sometimes I just don't know where to start or am timid and I'm scared to mess something up. I want to learn and am glad we now have the internet to give us a bigger knowledge base to draw from. Sometimes, I feel like I grabbed ahold of the steering wheel and i'm left to my own to find out if the wheelbearing is bad by trying to read the owners manual and the tech manual. I am really trying to understand how these radios operate but talking to my local club, I haven't found the elmer yet. So I appreciate everyone's patience when helping diagnose a problem. I saw earlier that there was recommended reading, maybe we could post a sticky with that that would be helpful. I guess if we could post things to help us down the road that would be great, like many of us I'm not looking for a handout but truely want to understand how these radios operate and want to be a HAM of days gone by where we repair, fix, and create, instead of just plugging our computer in and running a program. I bought my ts-520s because I didn't want to be dependant on computers and truely wanted to be a HAM operator not just an appliance user. Unfortunately I wanted to get on the air like so many others and bought an older radio cause the cost benefit analysis, hoping I could fix it and learn along the way, but without hands on mentoring, that can be very frustrating for both the person learning and the person with knowledge willing to teach but unable to convey their skills. As a new HF ham appreciating technology and wanting to understand where we came from I want to say thank you for helping and please be patient, we are a dying breed.

OK so I replaced the resistors, and yes, they were bad and had brown spots on them. I actually had replaced those back when I did the filter caps and forgot I did that. So I put in the new resistors, tube bias is again 60 mA. I tuned into a 50 Ohm dummy load and things appeared good. I made a contact on 40 m and got a good report. I tried later that night to switch to 80m and I get like almost no output. Switched back to 40 and again , little output. I switched the radio off, waited till the next day and tuned up on 40 and had almost 100 w out on CW into a dummy load. I left the radio on and after several hours the radio now only puts out about 40w. Is this an indication of bad finals? Can I use the 6146W's that I have, or should I just stick with 6146B's? I'm sure I will have to do the neutralization procedure regardless and will have to do some research on that. BTW, everything else seems fine on the radio, it still hears well. I'm using a full size G5RV with an LDG 200 tuner.

Dave,
You stated that you replaced the "filter caps," I am assuming you are talking about the HV capcitors?

Conduct the following simple tests:
How much drive do you have available? You should be able to get full swing on the "ALC" meter reading on all bands...if you can't, especially on the higher bands...your driver is going. With rig tuned properly(per operators manual), and key down in CW, does the drive fall off? If so, probably your driver(12by7a) is going.
Is the plate current dip (in CW) broad and shallow? If so, final amplifier tube(s) are going...especially with loss of output.
Does the plate current (Ip) fall off after a few seconds of key down? If so, probably finals.
After a "pop" or "crack" sound, I would retest the screen and cathode resistors on the final board. You may have suffered an internal failure of one of your final amplifier tubes.
Also, what is the "at rest" HV reading and the HV reading during transmit?
You may also have suffered a failure of one or more components in the final amplifier compartment, mainly: L-1, C-7, C-8. If your HV is good and you have good Ip, but your power output is low, I'd suspect one or all of the above. Several sources of replacement parts are available: hybridrestore"dot"com & k4eaa"dot"com. They come as a kit..so all three parts get fixed at the same time. A caveat: pay attention to what is connected to what/where!

Since you do not state if the rig is relatively new to you...any number of causes are possible. The above simple observations & tests is where you should start.
6146W is ok to use, but as you stated, you'll have to neutralize them

OK so I replaced the resistors, and yes, they were bad and had brown spots on them. I actually had replaced those back when I did the filter caps and forgot I did that. So I put in the new resistors, tube bias is again 60 mA. I tuned into a 50 Ohm dummy load and things appeared good. I made a contact on 40 m and got a good report. I tried later that night to switch to 80m and I get like almost no output. Switched back to 40 and again , little output. I switched the radio off, waited till the next day and tuned up on 40 and had almost 100 w out on CW into a dummy load. I left the radio on and after several hours the radio now only puts out about 40w. Is this an indication of bad finals? Can I use the 6146W's that I have, or should I just stick with 6146B's? I'm sure I will have to do the neutralization procedure regardless and will have to do some research on that. BTW, everything else seems fine on the radio, it still hears well. I'm using a full size G5RV with an LDG 200 tuner.

Dave and members who really want to learn!!!

Dave, your initial post back in July stated you dad had a problem with your TS-830. You later stated that when you checked for 60ma (meter switch set to IP in any sideband mode and any band), the meter pegged fully to the right. You then asked what was causing this problem?

First you and other members wanting to learn need to understand how the final amplifier cathode and IP meter circuit works. I'll use the TS-520/820 first, they both have two 10 ohm 1 watt resistors connected in parallel that results in 5 ohms of cathode resistance. I will then do the TS-530/TS-830 which both have four 20 ohm 1/2 watt cathode resistors wired in parallel for the same 5 ohms of cathode resistance.

Total resistance of resistors connected in parallel use 2 formulas

With 2 resistor in parallel, use the formula

R1 x R2 / R1 + R2

For more than 2 resistors in parallel, use the formula:

1 / 1/R1 + 1/R2 + 1/R3....= Rt (Resistance total)

If the resistors are the same value, say 20 ohms and there are 4 of them wired in parallel, you can simply use this formula

20 / 4 = 5

The last one is the easy way. Just because the last one is easy, don't relay solely on it, learn the other 2 formulas too!!!

I will be using Ohms Law formulas to calculate the voltage drops and current levels flowing in the cathode and the IP meter circuits. I will also use formulas to calculate resistance in series since the IP meter circuits are all series circuits.

I will use 60ma as the initial current level flowing in the final amplifier cathode circuit. The cathode resistance will assumed to be as close to 5 ohms as possible for all KW hybrid, 520, 820, 530, and 830 final amplifier cathode resistance. There are certain steps that must be takes and those steps must be taken in the proper order in order for the results to be correct. Failure to follow the steps in the proper order will result in your calculations being "wrong"! Oh, in series circuits, the same current flows through "each" resistance component!!

First, we must calculate the final tube's cathode voltage with 60ma of IP current flowing in the final tube's cathode circuit. We do this by using the Ohms Law formula:

E = I x R

where "E" is the unknown cathode voltage
where "I" is the 60ma of IP meter cathode current
where "R" is the 5 ohms of final amplifier cathode resistance

We replace "I" with .06, replace "R" with 5 which results in the following:

.06 x 5 = .3VDC

that's "300 millivolts". There are "1000 millivolts" in "1VDC". Did you know this? If not then you should!

The 520/820 meter's internal resistance is approximately 600 ohms. Not all meters have the exact same internal resistance. However, for this discussion I will use 600 ohms.

We first must calculate the total resistance in the IP meter circuit. The 2 resistance values are 3.3K for the meter multiplier and 600 ohms for the meter's resistance. Since this is a "Series' circuit we simply "add" the 2 resistance values together for a total of 3900 ohms:

3300 + 600 = 3900 ohms

Now that we have the total IP meter circuit resistance we can now move on to calculate the current that will flow in the IP meter circuit with "300mvdc" (.3VDC) of final amplifier cathode voltage applied to the IP meter circuit. We will use the Ohms Law formula:

I = E / R

where "I" is the "unknown" current flowing in the IP meter circuit
where "E" is the .3VDC cathode voltage applied to the IP meter circuit
where "R" is the "3900" ohms of IP meter resistance

.3 / 3900 = .0000769 amps

I'll round off the number to 77ua which will not make any "significant" difference in the math calculations.

"ua" is the term used to signify "microamps". There are 1000 microamps in 1 milliamp. There are 1000 milliamps in 1 amp. These are terms and values all hams should already know!!

Okay, now we calculate the voltage drop across the meter multiplier, 3.3K 1/2 watt resistor. We use the Ohms Law formula

E = I x R

same formula we used to calculate the 6146 cathode voltage. We simply replace the values as follows:

"I" is the 77ua of current, .000077
"R" is the 3300 ohms of resistance of the meter multiplier

.000077 x 3300 = .254VDC

That is "254mv" (mv stands for "millivolts"). There are 1000 millivolts in 1VDC. Again, something all hams should already know.

Now, does this mean that 254mv appears across the meter? Absolutely not! There is one more step you have to do in order to find the approximate DC voltage applied across the meter. That step is, we subtract 254mv from 300mv and we get 46mv applied to the meter:

.300 - .254 = .046VDC

Now the 530 and 830, they both have four 20 ohm 1/2 watt cathode resistors wires in parallel that produces an approximate same 5 ohms of cathode resistance. We do the same math, use the same formulas, to achieve the DC voltage and current values. The difference between the 520/820 and 530/830 IP meter circuit is the meter multiplier and the meter's internal resistance values are different in the 530/830. The meter multiplier resistance is 2.7K 1/2 watt and is in series with the meter's internal resistance of approximately 800 ohms. Some 530/830 meter resistance may be slightly less or slightly higher but again, for this discussion, I will use 800 ohms. The slight difference in meter resistance will not result in any significant differences in the math calculation!

The 530/830 have the same .3VDC is the cathode voltage at 60ma IP current. Therefore we use the same formula and the same current and resistance values:

E = I x R

.06 x 5 = .3VDC

The IP meter circuit resistance is found the same way as we did in the 520/820 except the resistor and meter resistance values are different. You simply add 2700 and 800 together and you get 3500 ohms (2700 + 800 = 3500). The 4.7K or 6.8K resistors seen on the final amp schematic, labeled R10 in both the 530 and 830 final amp schematics, are not used in the calculation and without them there will be no significant differences in the outcome of the math calculations so I simply do not include them in the exercise!

Since we have .3VDC cathode voltage applied to the IP "series" circuit of 3500 ohms, the current flowing in the IP meter circuit is approximately:

I = E / R

.3 / 3500 = .0000857 amps

I round off the current to .000086 amps. This will not change the results.

We now calculate the voltage drop across the 2.7K meter multiplier using formula

E = I x R

.000086 x 2700 = .232VDC

We subtract .232 from .3 which leaves .068VDC applied across the meter.

Why did the IP meter peg when you checked for 60ma of final amplifier no RF idling current? It's simple. When the cathode resistors failed, burnt open, the 6146 cathode circuit is "open". An open cathode circuit will allow the 6146 cathode circuit voltage to rise towards the tube's anode voltage. When this happens and the meter switch is set to IP, the only path for the 6146 current to flow through is the IP meter circuit. This results in the current and voltage levels in the IP meter circuit to significantly exceed the maximum voltage and current ratings of the meter, hence the meter slams and rest against the right meter peg! This is not considered "FS" (Full Scale). "Full Scale" means the meter point is pointing at the last right tick mark on the top current scale, NOT resting on the right meter peg!

Here's another quick example where using Ohms Law can be used to determine power input and output. All you need is the HV and IP meter levels as shown below. This example assumes the final amp plate HV is measured at +825VDC and IP current of 220ma after the transmitter is tuned up to maximum power into a 50 ohm dummy load. We use the formula and the above HV and IP current figures as follows:

P = I x E

.220 x 825 = 182 watts DC input

Since the KW hybrid final amps operate in Class AB1 which has a maximum of 60% efficiency, the power you can expect to be fed to the 50 ohm dummy load is approximately 109 watts.

182 - 40% = 109 watts

This assumes the transmitter is operating at optimum levels with good driver and final tubes!

These are only 2 of the many areas that hams who service their ham gear should have a solid knowledge foundation of. Try the above steps with your own KW hybrid or your Heathkit final amp. By the way, for those members who want to learn how to calculate total resistance, voltage drops, and current levels, in series and parallel circuits, I have videos on my website that show how to do this.

www.w5rkl.com/videos/

I apologize for the length of the post but thought it would be a good discussion for the member/hams who want to learn.

I remember the telltale "crack" when my first 520SE (first real HF rig, too) went out in about 81 or so....found the HV caps had blown out all over the bottom of the case.I scavenged a pair from a computer power supply (rather large computer, think it was a Series 10 from DEC), put them in and the rig worked happily away until I sold it for my first hollow state rig in 87 or 88. It was really a wonderful rig...now the 530 is having its own hiccups that I am slowly delving into. It takes time to do it right...no need to bother the crew here as I've been through lots of this before, including stuff on a rather lousy 520 (hiss, boo) that was not well cared for by its previous owner. I really wanted to get it running, too, but too many of the boards were actually cracked and smoked by misuse. I never felt I could trust it. Oh, well, back to troubleshooting....:)

Thanks for forwarding, Joe. Sad news indeed to hear of his passing.

Here's the obituary:

Neil Wayne Heckt,78, died after a long illness, Wednesday August 19 at Franciscan Hospice in Burien Washington in the presence of his wife.

Neil was born February 8, 1937 in Jasper, Minnesota to Velva and Milo Heckt.

He attended the South Dakota School of Mines and graduated from South Dakota State University and immediately embarked on a 34 year aerospace engineering career with the Boeing Company where he worked on the Apollo space program.

After retiring from Boeing he founded a successful new company Almost All Digital Electronics where he sold electronic products of his own invention that catered to amateur radio aficionados. He was highly regarded within that community.

Neil is survived by his wife Merlann (Kay) Heckt, his five sons, James, Richard, Steven, Andrew and Neil (Scottie); seven grandchildren, brother Orvan and many friends.

A service in his honor will take place Friday August 28th at 2:00 o'clock at Cascade Memorial in Federal Way, Washington.

Dear Group

I wish to inform you what a great asset we have in our group, in the form of Walter Dilley, who has taken over from Bob Mansker in supplying us with Hybrid Radio components.

Walter found, after much searching, the required components and sent them to me which I received today, to convert my BS-8 panadapter to a BS-5. This has been successfully completed and I intend posting pictures soon to the group.

Thank you greatly Walter. Your kind help is greatly appreciated. I highly recommend you to the group.

Dave,

Did you check the HV when you tune the transmitter up? If the HV caps had failed, possibly due to excessive pressure built inside the cap that ruptured the pressure relief on the bottom of the cap, then you would see cap residue on the bottom of the cap.

Now if the caps are okay and the pressure relief has not ruptured then you could try the following simple test on say 20 meters.

1. Connect the radio to your 50 ohm dummy load
2. Power up the transceiver and let it warm up for 15 to 30 minutes
3. Set CAR control to 12 o'clock
4. Set DRIVE control to 12 o'clock
5. Set Mode switch to TUNE (reduces the final amplifier screen voltage by 50%)
6. Set Meter switch to ALC
7. Flip SEND switch UP
8. Adjust DRIVE control for a peak meter indication, ignoring any scale, paying attention to the position of the meter pointer. If the meter pegs fully to the right, adjust the CAR control CCW so the meter pointer is pointing to 12 o'clock and continue adjusting DRIVE control for a peak meter indication.

Once the meter peak is achieve, leave the transmitter keyed for an additional few second while watching the meter. If the meter starts to drop slowly back towards zero then the driver tube is more than likely weak and needs replacing.

Leaving the transmitter keyed for a few extra seconds in TUNE mode will not harm the transmitter final.

Hello Fellow Group Members

Herewith the final posting on "How To" regarding this project. Please also refer to photos in the Album Section.

Converting the Kenwood SM-220 Monitor BS-8 Panadapter Module to a BS-5 Module for use with the Kenwood TS-520S

The first task is to download the Kenwood Station Monitor Model SM-220 Instruction Manual from any of the websites listed, when you perform a Google search.

If you do not already have a copy of the Kenwood TS-520S Service Manual, you can download this, but you will only need page 19 in particular, as this will show you the PCB layout of Board X48-1060-01 (IF Unit), where specific components are located.

Okay you are now ready to go:

Step 1:

You will need to open the station monitor by removing the top and bottom covers and locate the BS-8 Module inside a can, which is mounted on the side of the station monitor. Remove the can, by unplugging the 2 cables, unscrew all the screws, and remove the PCB from inside the can. Be patient and gentle. The clips can be tricky. Once the PCB is removed, put it to one side.

Step 2:

You now have to make the cable, if you do not already have one, to connect the TS-520S to your station monitor, to access the panadapter function. A photo of this cable can be found in the files section. The procedure to make this cable is described on Page 20 (Fig 8-4) of the Station Monitor manual. Cable IF #2 has a BNC connector made off on it and this will be connected to the Vertical Input of the Station Monitor and Cable IF #1 has an RCA male on it and this will be connected to the PAN Display input at the rear of the Station Monitor.

Step 3:

However there are 2 other parts to this installation which entails installing components and RG174U cable inside the TS-520S, so that you can perform Receive Signal Observation, namely:

1.) The TS-520 IF #2 Output Installation (Pages 10 & 11 of the Station Monitor manual). At this time you will need to reference Page 19 of the TS-520S Service Manual, as you will need to solder one end of the 22pF capacitor onto the Drain of Q4. This point needs to be located. As I did not have a terminal Strip (not available at any of our Electronics Shops) I made an in line soldering circuit. I have included this in the photo section. This is the only tricky task and needs one's full concentration.

2.) Transceiver Modification IF #1 Output Installation (Page 20 Fig. 8-5 of the Station Monitor Manual)

Work carefully and follow each step closely.

Step 4:

Converting the BS-8 module which you removed in Step 1, to a BS-5 module. Refer to Table 8-3 on Page 21 of the Station Monitor Manual.

I obtained 2 components from Walter Dilley (walter.dilley@gmail.com) who has taken over all Hybrid component stock from Bob Mansker, and these are:

· A 3.395MHz crystal (X1 part no. L77-0123-05) (Crystal CW T13-98 3395.0kHz) as found on the Car Unit Board (X50-0009-01) of the TS520/S/SE and

· A coil (T4 part no. L31-0286-05) (NB coil (A)) as found on the NB Unit Board (X54-1080-10) of the TS520/S/SE.

The rest of the components (5 Capacitors and 1 Inductor) I managed to obtain from my local Electronics Store. These components are listed on Page 21 in Table 8-3 of the Station Monitor Manual.

Desolder and remove capacitors C231 through to C237 as well as L203, L204 and T201 from the BS-8 circuit board. Work carefully especially when removing T201 as too much heat will lift the fragile tracks. Remember your SM220 may be close to 50 years old, if not older.

Solder in C231, C232, (No C233), C234, C235, C236, C237, the 3.395MHz Crystal (L203) (received from Walter), L204 20uH Inductor and T201 Transformer (received from Walter). T201 is specifically made for the 3.395MHz frequency. 2 Of the capacitors can be re-used but they are so cheap you might as well use new ones.

Completion:

Once all this is complete, you can test the functionality of the system by connecting the circuit board back in circuit with the Station Monitor, ensuring that the board is isolated from any metal. Connect the Station Monitor up to receive audio from an amateur station and monitor the speech coming in. My one photo shows the IF Trace coming in as well as the settings on the station monitor.

Congratulations, all is operational and now you can close up all covers. I saved all the removed components I removed in case I ever wish to convert

the module back to a BS-8.

Enjoy the fact, that your Station Monitor has full functionality, both transmit and receive signal monitoring.

Hi
I wanted to see if the "Proc" button on the TS-830 must be utilized for SSB or does it work without it?

I only see output on my wattmeter, and only make contacts if the button is pushed in (activate/on).

If this isn't required, I assume that the button is "dirty" and needs to be cleaned or replaced. I'd appreciate any input or guidance.

Thanks
John

with The proc. button out, you should transmit SSB voice with a little less punch . But not getting any replies? something else is wrong. Do you set the mic gain to just kick the ALC reading up on the meter on each sylable when you speak directly into the mic ??? My radio is Ham Radio...CW is Real Radio 73, John...K8JD

It was the curse of the old radio and a button getting dirty or oxidized.

If I pushed in the button, SSB worked, if I pushed it in and out quickly a handful of times, it'd work for a minute with the button in the "off" position.

I hit it with some non-residue (and plastic safe) contact cleaner, then a short while later made my first contact with it.

That 830 is quite a machine, my poor 530 is feeling neglected.

Thank you for your replies, everyone is always very helpful.

Topic: 53075 Message: 53075

A friend of mine dropped off his TS530SP for me to look at. When I power up the rig the S-meter pegs to the right and the unit appears to be in full transmit (no receive audio). I have both the mic and carrier knobs fully CCW, the RF gain control fully CW, as well as the heaters and SG switch off in order to save the finals. I have opened the rig up and the rig is in very good (clean) condition with no sign or smell of burnt components. I did notice the rig has the RL-1 relay still in place but I failed to notice whether it latched when I turned on the rig.

Normally one would use the REC/SEND switch to put the rig in transmit.Right now I don't have hand key or microphone plugged in either. The rig has not been used in a while so all switches and controls will need a good spritzing of DeOxit and work them through their paces. I tried the SEND/REC switch and it just quite have the normal click like you would hear so that is why I wonder about it being locked in the send position internally. Hence the need for DeOxit. I did tap on the RL-1 and the relay did not affect the rig being in transmit mode.

I recently had foot surgery so until I can get released to go to my hamshack upstairs it limits my ability to troubleshoot this problem. Has anyone had this issue and any ideas on what to try next.

Hi WB0CJB,

It's unlikely to be transmitting if you've got
the SG and heaters off. What about MODE switch
selection it's unlikely, even if it is in TX that
the meter would peg in SSB or tune mode? Is the
meter pegged regardless of which meter position
you set on the meter switch? Please clarify what
you mean about the SEND/REC switch. Are you saying it feels funny?

I think you need the manual, and at least a volt meter to go further.

Measure RF-1 on the AF board. Should be around 3.2vdc. Then measure the RFG voltage at the IF board. Then measure the AGC voltage at the IF board. Use a 10 to 11 meg input Z meter.

If you have good RF-1 and RFG and very low or no AGC bus voltage then you may have a bad contact on RL-1 aux control relay on the IF board. Other possibility is a bad Meter FET Q7 (not as common).

See the service manual to determine the proper Molex connectors and pins on the AF and IF boards.

You can temporarily touch 3vdc from couple of flashlite battery cells in series to the AGC Molex connector pin on the IF board to see if the receiver comes alive.

wb0chb,
It is quite possible that RL-1...the small flat pack on the IF board is bad. It controls many functions, it's hard to clean the contacts, they are small and delicate. You could try a spritz of contact cleaner followed by a shot of "canned air." This is usually a short term...if any fix. The other may be that the T/R relay...at times also called RL-1, is bad. It is under the metal shield next to the final board. Access is from the bottom...couple of screws..you may have to move some small wires...be gentle...remove cover...relay can be removed with slight rocking and upward force. the plastic cover can be removed to gain access to the contacts. Use clean stiff paper/card stock sprayed with cleaner and run it though ALL the contacts until clean, blow off with canned air. Spray a small amount of cleaner into the relay socket and insert and remove several times...then blow out with canned air. Now is a good time for magnification and bright light to inspect the contacts of the relay for burns/pitting.
RL-1 in its original form is not available. K4eaa"dot"com has a very well done replacement, that will more than likely, outlast many of us here..hihi

From I have read on Ken's web site the RL-1 is notorious for going bad in the 830 and 530 series rigs and can cause all kinds of issues. In fact I had just gotten a replacement RL-1 board from K4EAA for a Kenwood TS-120S. It uses 2 RL-1 boards so I will be ordering a couple more boards for when I get ready to do the surgery on the 120S. When I did the research on the 530SP I noticed there was an RL-1 and I immediately began to suspect that it may be bad.

Thanks and will keep you all posted.

The rig goes immediately into transmit upon turn on in each position of the mode switch when I turn on the rig. Even though the heater and SG switch is off the rig should be in receive until you flip the SEND/REC switch.

But when I can get to a manual and my DVM I can do further checks of the rig and the RL-1 relay.

I could be wrong but it appears to be a tap to feed the IF signal to a monitor scope such as the SM-220 with the BS-8 Pan Adapter.

I added a similar connection in my TS-520 3.395Mhz IF Unit to feed the IF signal to an added RCA socket on the rear panel. I then used a short length of RG-174 coax cable to feed the input on my Heathkit HO-13 Monitor scope set to 3.395Mhz IF.

Hello to group. I know this topic has been beat to death here, but just wanted a little input before I tear into my radio. Have an 830s with VFO230 attached. Frequency on 830s jumps at times as much as 1khz up and down on all bands. When I switch VFO230 to vfo it stops and is rock solid. Switching VFO230 back to main and frequency jumps again. Also I disconnected the VFO230 and frequency still jumps. I see that most of the culprits are 9v, fix switch, and vfo ground wiper on 830s. This looks like the vfo wiper to me since the 9v is also used in the VFO230 as best as I can tell. Any thoughts??

Steve.... Just get that VFO unit out of radio and clean that wiper....,Wiper on back side and then get a drop of good lub. in the front bearing assy... Just a drop or two......The VFO pops right out of the radio... There are steps and pictures that one or more group members have put in archives..
Then it is case of two screws under the "port" cover to pull cover off and there is the vari-cap right in front of you.. My VFO just had aluminum tape over "port".. Careful NOT to deform the wiper.... Just get good spray cleaner under the blade.. I know it's been said to put a dab of conducting grease under the ,now cleaned, wiper tab but not sure of good brand recommend...Maybe another of our members could help provide the brand name for you..Gently re-install the VFO and you are off and running....Neat repair....!

Good luck and 73's Mike (KD2DYY)

Mike and Steve,

The lubricant grease is NOT applied under the variable capacitor's shaft brass flexible connection but rather the lubricant grease is applied to the capacitor shaft's "bearings"!!

I use the following "conductive" grease:

/*DeoxIT L260Ap*//*Mechanical & Electrical Grease*/

I picked up a small "28 gram" container on eBay.

There is an eBay seller under eBay ad #400917617722 is selling the same 28 gram container for $15.69 "Free Shipping". This small container will last you for years.

I had the same problem in my Heathkit SB-303 solid state ham band receiver. I would thoroughly clean the variable capacitor's flexible connection but after a few weeks the instability would return. There are a few hams who suggest soldering a flexible copper braid wire from the capacitor shaft to the frame. While this would have cured the problem, I thought that method was a bit too much, there had to be a better way.

I found and purchased a small container of conductive grease (see info and eBay ad above), removed the LMO (VFO) from the receiver, thoroughly cleaned the flex connection, removed all grease from the shaft bearing end, and applied a very small amount of the conductive grease using the large end of a flat tooth pick to the bearings. I worked the grease into the bearings, paying close attention to ensure no grease fell into other parts of the LMO circuit or onto any of the capacitor's variable/fixed plate. I reinstalled the LMO back into the receiver, problem solved. That was well over a year ago and the LMO still tunes very stable without any instability in tuning.

As I said above, pay close attention to ensure none of the grease falls onto any circuit components or onto any of the fixed and/or variable plates as the grease is "conductive"!!!

There are two rotor shaft wiper contacts in the 530/830 VFO. One on outboard end and one on the inboard end of the air variable.

I would remove the shield can and clean both wipers with Deoxit D5. In severe cases a drop of full strength D100L may be required. I would also check the board mounting screws as very common for them to be loose. Be very careful reinstalling the fine thread shield can screws so you dont cross thread or strip them.

You can also take this opportunity to apply small amount of Tri-Flow with small tipped artist brush to the pinions and anti-backlash gears.

Lastly be careful re-installing the VFO back in the front panel so that you dont pinch the two sets of analog dial lamp red wires when you torque the 4 mounting screws.

Mike,
Crystals are indeed needed. Look further into the Operating Manual on Pg 21, section 4.15. The crystals are plugged into sockets that are on the FIX-VOX board that is on the underside of the rig(See Pg 42 of manual) Crystals can be obtained from International Crystals in Oklahoma City, OKThe crystals run about $25-30 EACH. There is a formula on Pg 21 of the Op Manual for figuring out what frequency the crystal(s) need to be. I've only seen two 820's with crystals installed here. The crystals are useful for constantly used frequencies...say a net or something. I would spend my money on a remote VFO-820

From: Mike W5RKL
Topic: 53098 Message: 53100

I agree.

Also, the operator must understand what positions the FUNCTION switch are set to determine how the crystal(s) and VFO control the hybrid transceiver frequencies. This is also explained in the operator's manual.

FUNCTION switch positions:

VFO = The internal or external VFO control both TX and RX frequencies. Normal setting for VFO control of both TX and RX.

VFO-R = The VFO controls Receive frequency while the selected crystal controls the TX frequency

FIX-R = The selected crystal controls the RX frequency while the VFO controls the TX frequency

FIX = Both TX and RX frequency is controlled by the selected crystal

The crystal simply replaces the VFO. The following are 2 examples of how to calculate the crystal frequency for a desired frequency and to determine what other band frequency the crystal may also operate on.

The formula, as stated in the manual, used to calculate the crystal frequency for a desired operating frequency is as follows. This applies to all TS-520 and TS-820 models:

/*5.5 + X - desire operatin*//*g frequency*/

"X" is the band switch position such as 3.5, 7, 14, 21, 28 etc

"5.5" is the VFO output frequency at the bottom of all bands regardless of the band switch setting. The internal and external VFOs operate over a frequency range from 5.5Mhz to 5.0Mhz regardless of the band switch position. This is also true for the VFO-520 and VFO-820 external VFOs.

Lets assume the operator wants to operate on the Maritime Mobile net, 14.3Mhz on 20 meters crystal control. The crystal frequency would be "5.2Mhz"

5.5 + 14 - 14.3 = 5.2

The crystal will also operate on 3.8Mhz on 80 meters.

/*5.5 + "X" - crystal frequency*/

The difference in this formula verses the first formula is the last value is the crystal frequency instead of the desired operating frequency. The crystal frequency in this case is 5.2Mhz.

5.5 + 3.5 - 5.2 = 3.8Mhz

I have one of the first TS 520. The internal vfo drifts slightly. I can hear a tone change on my cw stations and they tell me I am occasionally jumping around. I removed the side cover on the vfo housing and cleaned it with deoxit very carefully. Spraying, moving the dial, and blowing out residue. No problem with an external vfo. Where should I look nex?

Thank you Brian n NC

Topic: 53101 Message: 53103

Brian:

I forgot to mention that there are times that contact cleaner (even quality brand like DeOxit D5) applied to the air variable cap rotor shaft wiper contact wont fix the problem. Even multiple applications and several lock to lock rotations may not work.

For those times I apply couple of drops of full strength DeOxit D100L to the wiper with an artist paint brush. D100L is expensive, but the bottle will last most people a life time. It comes in small bottle with applicator brush similar to nail polish. I transfer couple of drops from that brush to tip of an artist paint brush which allows the reach that is required with VFO in place.

Terry K9TW

Mike W5RKL:

I need to get better at identifying who I am directing comments to. I was responding to Mike KD2DYY who talked about removing 2 screws (?) and cleaning the wiper on the "back" side. The shield can has 5 screws and there are two wipers (inboard and outboard ends). You can leave the shield can on and remove the aluminized tape from the wiper access port, but I never do that as I want to re-seat the PC board ground plane screws and completely lube the gear train, and sometimes if experiencing a lot of drift and cant tame it I will clean the PC board with alcohol or lacquer thinner. Dont know why that helps, but it often does. Lastly, some of these series VFOs have a star lock washer on the back shield can screw and I have found that washer floating loose inside the shield can more than once. I dont know if that washer is factory installed or not.

53108. Kenwood Hybrid Net Update (October 17, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-09-28 23:20:19 UTC
From: Mark Gilger
Topic: 53108 Message: 53108

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by me, WB0IQK. There
were 21 stations checking in under good band conditions.

We had the following number of radios checking in.

5 running TS-520(x)
1 running TS-530(x)
6 running TS-820(x)
4 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running a TS-830 with my L-4B AMP.

The Sunday net was run by me, WB0IQK. There were
11 stations checking in under fair good
conditions. We had the following number of radios checking in.

3 running TS-520(x)
1 running TS-530(x)
0 running TS-820(x)
4 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running a TS-830 with my L-4B AMP.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

I just ordered the D100l. Just curious. Seems like I have heard there are some no longer available caps in the vfo that also cause problems. Not sure if this applies to the TS 520. Is that true?
This weekend I plan to pull the ts 520 out of service and make your suggested cleaning. I also plan on adjusting the adjustment on the carrier board to hopefully put the cw filter where it needs to be.
thanks Brian kb4mng

Brian

All analog LC type VFOs use temperature coefficient capacitors to stabilize thermal drift. All of these VFOs have a warm up drift spec and a long term drift spec. KW did a good job of selecting a very high quality air variable capacitor and tank coil ceramic form. The unit is made from substantial gauge materials and stable mounting to reduce microphonics. That being said all the materials used exhibit a temperature coefficient including the PC board. Some are positive going and some are negative going. Some VFOs will drift high and some will drift low and a few will stabilize and cycle back and forth high and low.

Taming VFO drift is a bit of art and science. There is only so much time you can spend on a production line with this task. Part of the key is taking what works in the lab and replicating it with use of quality parts on the line. As I mentioned it starts with using a high quality air variable capacitor and a high quality tank coil former. Back in the day NPO, N, and type P TC caps were readily available and made by reputable capacitor manufacturers. Today hard to find these caps. Have to use COG units and can be hard to find the values needed to replace the original ones in your VFO.

That being said it is not likely that your drift problem is due to a bad TC cap on the PC board. If you want to play around with temperature stabilization you can determine which caps are TC type by where they are at in the circuit including where you see parallel combinations of caps that provide multiple RF current paths to reduce capacitor heating. If you look in the Service Manual parts pages you can tell which VFO capacitors are Class 1 or Type 1 Temp Coeff caps by the CC45 designator in the part number. They should also have a color dot on the top edge.

You could play around by bringing tip of soldering iron near these caps and see how much the VFO frequency changes. If you find a cap that exhibits significant sensitivity to temperature change it might me candidate for change out.

Again not likely that your drift problem is related to bad TC cap. I would eliminate dirty rotor shaft wiper contact, bad 9vdc regulated supply, dirty trim pots etc before I would worry about bad TC caps on the PC board. As I mentioned when all else has failed I have had some success by cleaning the PC boards with alcohol. This may eliminate leakage paths on the component and foil sides?

Also, VFO drift and VFO frequency jumping around or VFO dropping out are very different things with different causes.

Lastly, some folks who like to operate digital modes cant live with even normal spec warm up and long term drift so they install "huff-n-puff" VFO stabilizer circuits in their hybrids. Two popular units are employed and have been discussed here in the past. One caution is these units can produce "birdies" in the VFO tuning range which may or may not be objectionable.

Suggest you repeat the wiper contact cleaning and clean the 9vdc and RIT carbon trimmer pots as first step and monitor the 9vdc to make sure it is not drifting.

Topic: 53075 Message: 53115

Paul WB0CJB:

Couple of questions and then suggestions:
1. Did you validate that the rig is in TX mode by observing that the relay armatures are changing state (physically moving) when you turn the rig power switch ON?
2. Is the Mic PTT Lock button depressed/engaged?
3. Is the VOX turned to the ON position?

If the answer to Q1 is Yes and the answers to Q2 and Q3 is No then very likely you have a shorted Q12 relay switching transistor on the Audio Board. When you roll the AF board over to replace Q12 suggest that you also replace back EMF diode D10.

If the rig is in TX mode on power on it is good idea to turn off Heater switch as you have done. Especially to avoid damaging the Driver tube which runs Class A at near full max plate current and cannot stand protracted keydown operation.

A pegged S meter in TX mode has nothing to do with bad Q12 switching transistor. Suggest you troubleshoot in this manner using a 10meg DMM or 11meg VTVM: (Note: Not all DMMs are 10 meg input Z on all ranges)
1. Measure the ALC voltage at Molex Conn 9 Pin 1 on the AF board. Assuming that RF-1 is set to 3.2vdc you should read approx 2.6vdc at ALC leaving the AF board.
2. Measure ALC voltage arriving at IF board at Molex Conn 14 Pin 1. It should be approx 2.6vdc.
3. Measure the ALC bus voltage at Gate 2 of Q2 TIF amp.It should be approx 2.6vdc. Q2 is a flat pack dual gate mosfet. G2 is upper left lead looking down on the package with front panel facing you. See the X-ray view of the IF PC board for location of Q2. If there is no ALC voltage at G2 of Q2 then most likely you have a bad contact in RL-1 aux control relay on IF board. I would replace this relay with Ken K4EAA new relay board. Could also have a bad Meter FET Q7. Can eliminate bad Q7 if the S-meter works in RX mode with off air signals or with the Marker signal.

Lastly, when measuring ALC bus voltage at AF Board Conn 9 Pin 1 and you dont have 2.6vdc and want to troubleshoot that problem the schematic has a major error on it. It shows at the Collector of Q31 ALC amp -101.7vdc in RX and -65.7vdc in TX modes. If we were to apply that level of negative voltage to G2 of TIF amp then would never have a transmitter! Actual voltage at Collector of Q31 will be close to +2.6vdc. When 6146 grid current flows and Q31 turns on it produces approx -1.0vdc at its Collector which bucks the RF-1 level which then reduces the control voltage to G2 of TIF amp which ultimately reduces the RF drive. Not sure how these kind of significant errors creep in. If you were to find a high negative voltage at Conn 9 Pin 1 then would have a shorted Q31 which is not common.

I also tried to check in Sunday's net, actually on Sunday, but Marc was unable to quite make out my call, N4RCC. I am located in the Panhandle of N. Florida and I am sure I heard Marc say he was on a 20m beam and was pointing West. Maybe a quick spin of the ol' beam would benefit some of us.. I was able to hear most of the stations calling in and was actually surprised no one bothered to relay when Marc kept trying to get my call sign right...
But on a good note, I was able to check into the Saturday net.

Thanks Marc for running these nets and keeping the hybrids on the air!

I recently acquired a beautiful one-owner 520SE. It worked great for a day, but the next time I tried to tune it up there was no carrier signal. In TUNE mode SEND, advancing the carrier control produced no increase in IP. I checked the CAR out pin on the CARRIER board, and found a 0.8V signal. All frequencies were "spot-on" for each mode. I suspect there is a problem on the GENERATOR board. Are there documented problems with the carrier signal not reaching the 12BY7 driver tube?

I agree also that this is not a good choice of frequency. 7.2 and up is shared with many broadcast stations - it is extremely unlikely I would hear the net in Australia at all, as any time after about 6:00PM here that part of the band is unusable till the following morning.

Bill,

Have you tried cleaning the FUNCTION and MODE switch wafers and the pots with DeoXit D5 contact cleaner? Use just enough cleaner to do the job, do not over spray. Follow all cleaning processes using canned air available at Walmart's Cell phone, TV, and DVD/game department or compressed air to remove any/all cleaner residue.

Read and adhere to the caution/warnings on the cleaner can's label!!

Bill:

It is highly unlikely that you dont have approx 800mv carrier signal at the Gen board if you have it at the Carrier board due to short 3 to 4 inch coax run involved, but I would measure to confirm. If you decide to troubleshoot the Gen board here are voltages that you should find in Tune/CW mode at the associated wrap terminal posts:

1. CAR = 800mv rf volts or more
2. BM = 0.0vdc with Car level pot full CCW and 0.60vdc with Car level pot full CW
3. CV = 0.0vdc with Car level pot full CCW and 9.0vdc with Car level pot full CW
4. RLT = -1.9vdc in RX mode and +9.0vdc in TX mode.
5. RL = 0.0vdc in RX mode and +14.7vdc in TX mode.

One of the most common problems is RLT does not switch from negative to positive voltage due to dirty contacts on RL-1 Aux control relay located under the VOX and Marker boards.

Once radio is operational again I would record normal as found voltages in notebook or mark on your schematic for future reference.

Mike, et al,

I have solved my "missing carrier" problem, but am somewhat embarrassed to admit how I did it Since the radio is new to me, I had to familiarize myself with its operation. I was under the impression that the narrow/wide filter switch pertained to side band operation, I chose to set it to narrow. However, I discovered that narrow also affects the TUNE function. The carrier signal goes through the CW filter in TUNE and CW modes. If the switch is set to narrow, but there is no narrow CW filter, the carrier goes nowhere. Switching to WIDE solves the problem. Everything is now working fine. Thanks for your suggestions.

Terry,

Thank you for your reply. My problem was trying to TUNE with the wide/narrow switch in the narrow position. Being new to the rig, I assumed that switch pertained to the SSB bandwidth, but it pertains to the CW filter bandwidth. Since there is no optional narrow bandwidth filter installed the carrier signal doesn't continue passed the empty socket. Therefore, no signal to the 12BY7. In the wide position everything works fine.

Bill,

Quite often previous owners remove the CW filter (if the radio is equipped with the CW filter) to sell the filter separately for added money when selling their KW hybrid. Unfortunately not many sellers move the BROWN wire from the IF Unit's CW terminal back to the IF unit's SSB terminal so you and other new owners will not experience the problem you did.

I mean no disrespect Bill but this is another reason why I more often than not recommend new KW hybrid owners should spend time thoroughly reading the operator's manual before attempting to operate their newly acquired KW hybrid transceiver. Doing so would not only show the operator the controls, what the controls are for, and discuss how to use them but also would have pointed out the CW filter installation steps and the filter installation wiring changes that are required. Reading the CW filter installation steps would hopefully trigger the new owner to check for the presence of the CW filter and the IF Unit's BROWN wire connection. Never assume anything, always check to be sure and that includes checking for the presence of the CW filter and whether the IF Unit's CW filter BROWN wire is connected properly based on the presence or absence of the CW filter.

I was able to get the rig on the bench and checked all switches and made sure nothing was on (VOX off, SG off, heaters off, mic and key unplugged, SEND/REC switch in REC position). Turning on the unit I observed RL-1 on the IF board latch for a sec then unlatched. I connected an antenna to the rig and could hear signals which told me the rig was not going into transmit at turn on. With a DMM I checked RF-1 on the AF board (read 3.16V). I checked the ALC on the IF board and it read 2.29V. The voltage on gate 2 of Q2 also read 2.29V. I checked the voltage on Q7 and the drain read 8.99V and both the source and gate read 2.29V instead of what the schematic reads (2.6V on the gate and 5.3V on the source). I am suspecting a shorted Q7 due to the source & gate reading the same.

While I had the unit upside down I pulled the cover off the T/R relay and got the cover off. I tried to clean the contacts as best as I could and looked at the contacts. One set of the transmit contacts appear to have been burned some. Is there a replacement relay available for the T/R relay in case the relay has to be replaced?

While I have the IF board out so I can replace Q7 should I go ahead and replace the RL-1 relay? The receive sounded pretty good but I couldn't tell with the meter pegged on receive.

In working order, used strictly for CW and due to health problems the owner can't pound fist any more. Has offered to demo the rig at his shack, so I'm suspecting it's in pretty good shape. Recently used, so it hasn't been sitting for all that long.

Looks like NO microphone.

CW filter (haven't asked which one)
installed. It's on craigslist at

http://evansville.craigslist.org/ele/5227811174.html

if you want to have a look or contact the owner yourself.

HE WILL NOT SHIP IT. It's pick-up only. If someone on the list wants it and has to have it shipped, I can pick it up for you and take it to the local UPS store or similar, for them to pack it up and ship if for you. You'll need to make arrangement to pay the owner and the UPS or other shipping place, I'll do the pick-up and transfer, no extra charge.

Contact me off the list if you're interested and need the pick-up.

OK you are now saying that the rig is not keyed with power on and is in RX mode and you can copy signals even though the S meter is pegged. However you should not be seeing any momentary movement of the RL-1 relay on the IF board. I have never seen one with an armature mechanical problem but suppose it could be hanging up. I would replace it with one of Kens K4EAA new relay boards with plug in relays while they are still available. If not a problem now will very likely be in the future.

Very unusual for S meter to be pegged and not be due to the AGC bus being pulled down very low. If the AGC bus is pulled down low you should not be able to copy any signals. So it sounds like a metering circuit problem and not a AGC bus problem. Can you get on the CBE leads of Q8 meter driver on IF board. ALM or M on Molex conn 10 is same as the Collector.

OK to measure and set RF-1 in RX mode but you dont want to measure ALC bus in RX mode. You want to meausure AGC bus in RX mode (I suggested that at one of my first responses to you). Measure RFG at the IF board and see if the voltage varies with the RF gain pot. Measure AGC at IF board.

Normal failure of Q7 meter FET would be a short that would pull the AGC bus down to zero vdc and there would be no RX mode as the dc control voltage (AGC) to gate 2 of the RF and IF gain controlled devices would be so low as to turn them off.

You talk about the Ant TR relay and it is not easy to clean and very easy to bend the movable leafs and ruin the relay trying to do so. Only viable choices are to replace it with a good used pulled original relay that can be easier to clean before installing or to sub it out with a socket and MX-2P relay pulled from a TS830 or modify it with an NTE relay as Jan N8CBX or others have done. Installing the 830 relay config is not too bad a job. Just need to clean the MX-2P before installing it.

Lastly sometimes if the Product Detector carrier has not been properly nulled it will leak back the IF chain to the AGC detectors as if it were a very strong off air signal and will turn Q6 AGC amp on very hard and pull the AGC bus down. What happens if you turn the AGC to the OFF position? You might want to adjust null trimmer cap TC-2 of Product Detector as described in the Service Manual.

One other thing I forgot to ask.

Have you tried adjusting VR-1 and VR-2 S-meter trim pots? Especially VR-1 in RX mode with rig on dummy load. VR-1 is the zero set pot and it is possible to mis-adjust it to drive the meter full scale deflection. VR-2 is set for S9 indication with 50uv input from RF sig gen or use the Maker in absence of calibrated sig gen.

If you have close to 2vdc on the AGC bus then S-meter should indicate close to S9 and not full scale deflection.

The main dial and sub dial on my 520SE are offset by 4 kHz. Curiously, this situation is identical to the picture of the front panel in the user manual. With the sub dial set to 200, the main dial reads 204. What am I missing? I thought I could simply remove the main dial knob, and shift its position on its shaft to read 0, but no joy - the two screws holding the knob in place are on there to stay. If I get to aggressive, and strip the notch in the set screw, I am sc---ed (pun intended). I suppose this is "nit picking", bit it bugs me.

There are 3 models of the TS-520. If you do not know the exact model of TS-520 you have, simply look below the front panel VFO knob and you will see in large letters and numbers, the actual model of TS-520 you have.

The first model is the TS-520 which has a White dial, does not have 160 meters, and came standard from the factory with the 13.6VDC DC to DC module mounted on the rear panel.

The second model is the TS-520S which has a dark dial, it has 160 meters, and the 13.6VDC DC to DC module is now an "optional" item.

The third and LAST model is the TS-520SE which also has a dark dial, has 160 meters, but can only be powered from 120VAC or 240VAC (rear panel switch select).

Each individual model has its differences. The above are only a few of the differences each TS-520 model has. Switches were change, switch locations on the front panel were changed, and bands were added. This is why it is important that you pay attention to and provide the actual model of TS-520 you have when asking for help or reading a response pertaining to a TS-520 model. It's quite possible the information contained in a response may not apply to your TS-520 model.

I have the operator/user manuals for all 3 TS-520 models on my website under "Manuals and Document" link at the top of the page.

W5RKL http://www.w5rkl.com

http://www.w5rkl.com

W5RKL http://www.w5rkl.com w5rkl@yahoo.com

View on www.w5rkl.com http://www.w5rkl.com
Preview by Yahoo

All 3 models, when operated from either 120VAC or 240VAC (rear panel select), have the same DC and PEP input power levels

CW - 160 watts input
SSB - 200 watt PEP input

Power input levels will be less when operating the TS-520 or TS-520S from 13.6VDC when equipped with the DC to DC module.

CW - 90 watts input (approx power output in CW mode will be 54 watts (90 - 40% = 54)
SSB - 120 watts PEP input

The above power levels assume the TS-520 model is properly aligned, has good driver and final tubes and the final amplifier has been properly neutralized.

I checked the RF gain control both fully clockwise and counterclockwise and it does not affect the meter. I turned VR-1 and VR-2 both fully counterclockwise and the pots do bring the meter just off the peg but is still full scale. This is what I have found in checking voltages on Q6 and Q8:

Q6 emitter & base both read -5.8V; collector reads 2.3V (service manual shows 5.6V should be on the base; E-B short on Q6??)

Q8 emitter reads 4.61V; base reads 3.94V; collector reads .46V

I measured the AGC and it reads 2.3V. Turning off the AGC does not change anything.

Measuring RFG on the IF board while adjusting the RF gain control the voltage reads .16V (CCW) to 3.19V (CW). Adjusting the pot through its full travel the voltage does change on the RFG terminal but the meter still does not move. The RF gain pot has no affect on the signal level on receive.

I did go ahead and change out RL-1 on the IF board. Adjusting TC-2 in the product detector section as per the manual does not change anything.

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by me, WB0IQK. There
were 22 stations checking in under good band conditions.

We had the following number of radios checking in.

4 running TS-520(x)
4 running TS-530(x)
3 running TS-820(x)
5 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running a TS-520s with my L-4B AMP.

The Sunday net was run by me, WB0IQK. There were
14 stations checking in under fair good
conditions. We had the following number of radios checking in.

6 running TS-520(x)
1 running TS-530(x)
1 running TS-820(x)
4 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running a TS-520S with my L-4B AMP.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total = 142, Sunday☐s total = 88
December 2014, Saturday☐s net total = 92, Sunday☐s total = 86
January 2015, Saturday☐s net total = 110, Sunday☐s total = 84
February 2015, Saturday☐s net total = 103, Sunday☐s total = 98
March 2015, Saturday☐s net total =80, Sunday☐s total = 51
April 2015, Saturday☐s net total = 59, Sunday☐s total = 29
May 2015, Saturday☐s net total = 79, Sunday☐s total = 48
June 2015, Saturday☐s net total = 70, Sunday☐s total = 38
July 2015, Saturday☐s net total = 26, Sundays☐ total = 56
August 2015, Saturday☐s net total = 73, Sundays☐ total = 65
September 2015, Saturday☐s net total =66, Sunday☐s total = 23
October 2015, Saturday☐s net total = 22, Sunday☐s total = 14 (Month to date)

Nothing wrong with Q6 AGC amp. The schematic is wrong. The base and emitter will both be close to negative -5.8vdc. All other items look OK.

I think you gave the D-G-S dc voltages for Q7 meter FET in an earlier response?? You should see something on the order of 9-3-5.5 vdc. Please repeat Q7 measurements and report back. I suspect you have bad meter FET.

Normally when Q7 meter FET is bad the Gate lead and AGC bus will read very low (around 1.5vdc or less) and you wont hear any off air signals unless very strong and have to run AF gain near wide open to hear them.

Q7 is a 2SK19-GR. You can commonly find them off Ebay. If not then have to use NTE sub.

Can you place two 1.5 volt batteries in series and apply negative lead to chassis and positive lead to AGC bus (at Molex Conn 6 Pin 3 purple lead wire). I suggested this very early on and never heard back. If S meter comes off the peg and now have normal audio level with off air signals then very likely Q7 meter FET is your problem.

53152. TS830S: a few small things won't work

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-10-05 13:44:50 UTC
From: Martin Jangowski
Topic: 53152 Message: 53152

Hi folks,

my TS830s is working fine, only a few things are not quite as they should be:

- the notch filter has no effect whatsoever. Trying to adjust the thing following step 24 (L10, VR1@AF-Board) in the service manual gave no audible effect. Is this adjustment very difficult? Any measurements with scope/freq. counter possible?

- Noise blanker has no effect on audio, even with sporadic "woodpecker" signal on 20m. Trying to adjust is following the SM didn't give any effects on the audio.

- VOX not working. Sometimes knocking on the mike sets it off (with sensitivity full cw), but mostly not. There is no adjustment procedure in the SM, I'm going to check the VOX-switch, the wiring and the working of the pots first.

Any helpful ideas?

Martin DB2MJ (who got several positive remarks about modulation and good signal quality in QSOs).

Topic: 53152 Message: 53153

Martin:

1. Notch Filter. Is exact copy of circuit used in Collins 75A4 receiver. Can adjust for lowest audio level in the speaker, lowest S-meter reading, or highest AGC voltage. I prefer lowest S-meter indication. L10 sets the frequency and VR-1 sets depth of notch. Adjustment is a little touchy, but not that bad. Can use RF sig gen or the Marker to produce the Heterodyne. Here is my procedure:
A. Set front panel knob to 1200
B. Connect freq counter to external speaker jack lead on inside of rear panel.
C. Either use RF sig gen or Marker and adjust the VFO for 1000hz on the Freq Counter
D. Adjust L10 and VR-1 for lowest S-meter indication.
E. Should be able to get to Zero indication and volume of 1000hz note in speaker greatly reduced.
F. Now leave VFO alone and adjust front panel knob back and forth around 1200 and should get deep null close to 1200. Move knob slowly to get the feel of what to expect.
G. Should now be able to vary the VFO for different hetrodyne tones (lower or higher) as if someone is tuning up on your QSO and should be able to move the panel knob either direction (depending on LSB or USB) from 1200 position and produce deep null.

2. Noise Blanker. Is an Impulse blanker and wont affect Wood Pecker or QRN. It is designed for electrical arcing like engine spark plugs, electric fence, cracked distribution pole line insulators etc. What are you using as your noise generator to perform the SM procedure? If no pulse noise generator then you have to use an appliance that has a commutator and brushes. The older and dirtier and more sparking at the brushes the better. Sweeper, blender, mixer, hair dryer etc will work. If you have a pulse generator (I use Rigol Abitrary waveform generator) set if for 480hz, 250mv, and low duty cycle around 5% so so you have series of short duration fast rise time pulses. Adjust T1/T2 for lowest S-meter indication.

3. VOX. Should be able to disconnect the Mic and set the VOX gain pot to 1200 and use your finger tip to just touch bottom right hand pin inside the mic connector on front panel to actuate the relays. Should be very sensitive. If have audio generator can troubleshoot by injecting approx 50mv at 1khz into VX-1 at IF board and then on to VX-1 at AF board.

Bill,

You may find this descriptive paragraph from the W0NTA website page on tuning KW hybrids helpful:

"Objective:

The objective in tuning a radio with a tube final amplifier is to set the proper drive (ALC), tune the final amplifier to resonance (PLATE), and set the load (LOAD) control for the proper level of plate current in the final amplifier. In the case of the Kenwood Hybrid radios, this means a final loaded plate current (IP) of 225ma. There are three controls that will accomplish this objective - the DRIVE control, the PLATE control, and the LOAD control. When these controls are properly set, the radio will put out a strong, clean signal."

When you tune the PLATE control for the dip, you should be reading plate current (IP meter setting) on the meter and adjusting the PLATE variable capacitor for the MINIMUM plate current reading (not zero!) on the final tubes (typically 6146B type). That's the "dip."

Achieving the minimum plate current at a given frequency means that the tuning circuit in the final amplifier is adjusted to resonance, or the point of maximum power transfer from the final tubes to the load (antenna or dummy load). You want to do this quickly, as the tubes can draw high current when the circuit is not resonant and this can damage the tubes if you let it go on too long.

This is one reason why the KW Hybrids have a "TUNE" position-this allows you to adjust for resonance (the dip) with the tubes operating at less plate current to protect them and the circuitry before you tune up to full power in the CW mode position.

The best thing to do is read the manual carefully for your specific radio. The 225ma plate current for the final tubes is a good value for some radios, but the proper current for 100W output can vary a little with the type radio you have, even with the same final amplifier set up.

Most of the Kenwood hybrid manuals recommend that, after dipping the PLATE current, you then switch the meter to RF and alternately adjust the PLATE and LOAD controls for maximum relative power output, as indicated on the meter when it's in the RF setting. This will provide 100W of output, or thereabouts depending on the condition of your tubes. This is what I do, but there are differing opinions on whether to do this or tune to a specific plate current with the LOAD control. I figure the Kenwood guys did it this way for a reason, so it's what I do.

Hope that helps!

73

Bill:

DIP = Nadir

Your TS520 Operating Instruction Manual provides you with the answer. Look at the parens in the Plate Tuning paragraph. DIP means Minimum Ip reading and not just at the point where the plate current starts down. The manual in addition to stating this also gives a nice visual or graphical picture in Figure 10 which shows you that the minimum Ip level is what your are adjusting the Plate Tuning capacitor to attain. If you adjust the capacitor either cw or ccw from that minimum level of plate current you can see by this graph that the plate current starts back up.

At minimum Ip this means that there is now RF current circulating back and forth between the Plate Tuning Capacitor and the Tank Inductor in the Pi-Network at an RF rate and the 6146 Final tubes are providing pulses of current to sustain this oscillation. Too many keystrokes required to describe what happens next when opening the Plates of the Plate Load capacitor which is in parallel with the load (antenna or dummy load) and start transferring RF current from the Tank to the load. Have to hit the ARRL Handbook and other RF communications fundamental texts to learn about this.

Go to You Tube and watch Alan W2AEW #153 video to see how to load your hybrid. One of the better if not best videos.

Just remember during loading to keep your keydown time to under approx 10 seconds at each step. This will ensure you dont damage the Driver tube or the Final tubes. With practice this will become very easy to perform.

On my website I explain why you want to literally follow the loading instructions in your Operating manual and why KW gave us the RF relative power meter position.

I took and put 3 volts on the AGC line and the S-meter dropped to S9+35 dB. The receiver also marked a noticeable improvement. While I had the 3V connected I tried adjusting VR1 & 2 and both varied from the S9 +35dB point to full peg position. The RF gain pot did not make any noticeable difference. But my thinking is that until I get Q7 replaced thats as good as it will get. This morning I will see if the local parts house has an NTE133 in stock. Thanks to your help I can call the owner this morning report that his radio is comng back to life.

Since I didn't have a extra transistor in my stash I went and oiled the fan, sprayed the pots and switches, and looked at the coupler on the bandswitch. I had noticed the bandswitch was loose and of course it was cracked on the end closest to the final section. So as I need a couple of RL-1 relays for a TS-120S I have waiting to be worked on I will get another coupler and change it out once it arrives.

As I was taking the cabinet off I noticed 2 of the 4 feet on the side of the radio are cracked. Anyone know of a good source of replacement feet? I saw where K4EAA had replacement feet but from the picture it looked like the feet he had for sale were for the bottom of the unit.

OK it appears that you have a very hard fault on the AGC bus and it is very unusual for a 3volt battery supply which is low Z and high current not to be able to bring the S meter off the peg and back down close to zero and restore full receiver gain. Of course there would be no agc action and RF gain pot wont have any effect as it is a high Z power source due to supplying the AGC bus thru a 2 meg resistor. Paralleling it with a low Z power supply will essentially cancel its effects.

Only being able to bring S-meter off peg and down to +35 is not typical when powering bus with 3VDC battery or a regulated bench supply.

If you have 3 batteries try applying 4.5vdc and see if you can get S meter close to zero. Applying 4.5 vdc to the bus and Gate 2 of its gain controlled devices will not harm them. Make sure the Marker is turned off.

You can also measure the AGC bus resistance to chassis ground with the power off and it should read close to 2.2 meg ohm. Unusual for any of the AGC time constant electrolytic capacitors to be very leaky or shorted.

I would go ahead and replace Q7 as a starting point. After replacing Q7 you will need to perform the S meter alignment as noted in Step 17 of the Service Manual. If you dont have a good calibrated RF sig gen then will have to use the Marker signal and wont be able to make the L8 adjustment for S1 indication. Can of course set Zero and set S9 and just call it good enough.

I checked the AGC line with the power off and the resistance read 440 ohms, unlike the 2.2 Meg you mentioned. I unplugged the Molex connector and again checked the Molex connector on the IF board (it again read 440 ohms). The Molex connector with the harness going to the RF board read infinite resistance.

After reconnecting the Molex connector I applied 4.5V to the AGC bus and the S-meter went down to S-8. I checked Q2, Q3, and Q4 voltages on all four pins and they read pretty close to the schematic. Rechecking Q7 I read 9V, 2.3V, & 2.3V. From what I can ascertain there doesn't appear to be anything that could load down the AGC bus but until I can get the transistor changed out anything is possible.

OK seeing 2.3vdc on both the Gate and Source of Q7 tells you that the Gate is Shorted to the Source and that is why you are seeing 400 ohms to ground on the AGC bus and why you cant drive the S-meter to zero by applying 4.5 vdc from batteries to power the bus. Being able to drive it to S8 should give you pretty normal receiver audio level.

Infinite resistance reading on the AGC bus on the RF Board is good.

When you remove Q7 before installing the new FET measure the resistance from AGC to ground again and you should find that the 400 ohms is now at 2 meg ohm.

Make sure if you use a sub that the DGS leads are not transposed.

I thought it was all explained in the manual sufficiently. If it can't be understood after perusing the net for further answers, of which there are plenty, then is a hybrid rig the right sort to be operating?

David G4TUP.

HI
Help
J HAVE UN OLD TS-520 ,

IN TUNE MODE

SWITCH METER ON IP POSITION ----- NO READ THE " IP" CURRENT
SWITCH METER ON ALC POSITION ------ OK ALC LEVEL

IN CW MODE

SWITCH METER ON IP POSITION ------ READ THE IP CURRENTE 225MA
SWITCH METER ON ALC POSITION ----- READ LEVEL ALC
SWITCH METER ON RF POSITION ------ READ LEVEL RF

QUESTION : WIICH IS THE PROBLEM BECAUSE I DON'T READ THE CURRENT "IP " IN TUNE MODE

THANK YOU TO ALL FRANCIS IK0IRE

I would think the screen voltage to the finals could be missing in tune.

Check resistors R5 and R6 on the X43-1110-00 board.

Tim

It's easy to verify the presence or loss of 6146 screen voltage on pin 3 of either 6146 tube socket.

Connect a DC volt meter set to measure +200VDC or higher, RED meter probe to pin 3 of either 6146 tube socket and BLACK meter probe to the chassis. Place the MODE switch to CW or either side band modes, the approximate DC voltage should be +255VDC. Leave the meter connected to pin 3 and chassis but change the MODE switch to TUNE. The DC voltage on the meter should decrease by approximately 50%. It is NOT necessary nor required to key the transmitter when measuring the above voltages on the 6146 tube sockets.

If the DC voltage on pin 3 of either 6146 tube socket is in fact found to be 0VDC then check for an open R6 on the HV Unit. If R6 is found to be open or a very high resistance, replace both R5 and R6 resistors on the HV Unit. Don't rely on R5 to be okay to keep, replace both resistors.

HV Unit resistors R5 and R6 form a series resistive voltage divider. The Rectifier Unit's "210A" approximate DC voltage applied to the HV Unit's "210" terminal is +255VDC. With +255VDC applied to the HV Unit's "210" terminal, a total current of 2ma flows through the series resistive circuit.

You can calculate the approximate 6146 pin 3 screen voltage in TUNE Mode by performing simple Ohms Law formula math using a simple calculator (Windows calculator works fine).

First, calculate the total resistance of R5 and R6 voltage divider series circuit which is 112000 ohms (56000 x 2 = 112000). Series resistance simply adds.

Next, calculate the total current flowing in the series circuit which is approximately 2ma and using the Ohms Law formula:

I = E / R

"E" is the +255VDC HV Unit's "210" terminal DC voltage applied to the series voltage divider
"R" is the total resistance of the series circuit (56000 x 2 = 112000)

255 / 112000 = .002

The same 2ma flows through both resistors R5 and R6.

With +255VDC applied to the HV Unit's "210" terminal and 2ma of current flowing R6, a voltage drop of approximately +112VDC will occur across R6. You can calculate this using Ohms Law formula:

E = I x R

"I" is the 2ma of current
"R" is R6's 56K resistance

.002 x 56000 = 112

To calculate the approximate DC voltage at the HV Unit's "TUNE" terminal, you simply subtract +112VDC from +255VDC which should result in an approximate DC voltage of +143VDC found on the HV Unit's "TUNE" terminal and pin 3 of the 6146 tube sockets.

255 - 112 = 143

The above DC voltages, R5 and R6 resistance values can be different due to age of R5 and R6 resistors and the actual DC voltage applied to the HV Unit's "210" terminal.

If R6 is found open then there will be zero volts on the HV Unit's "TUNE" terminal resulting in zero volts on pin 3 of each 6146 tube socket resulting in an IP meter indication of zero with the transmitter keyed in TUNE MODE.

Loss of 6146 screen voltage in TUNE mode, however, will NOT prevent the operator from achieving a peak ALC meter indication when adjusting the DRIVE control. The loss of 6146 screen voltage in TUNE mode prevents current flow in the PLATE circuit and a small amount of current flowing in the screen circuit ONLY. It has no affect on GRID current that results due to a positive segment of the driver stage's RF sine wave that causes the grids (pin 5) of the 6146 final tubes to become positive resulting in grid current flowing in the final tubes (cathode to grid)

One might be confused by my statement:

/*If the DC voltage on pin 3 of either 6146 tube socket is in fact found
to be 0VDC then check for an open R6 on the HV Unit.*//*
*/
That statement should have read:

/*If the DC voltage on pin 3 of either 6146 tube socket is in fact found
to be 0VDC in TUNE Mode then check for an open R6 on the HV Unit.*/

I left out the words "/in TUNE mode".

/Sorry for any confusion.

Greetings all,
I would like to share some good news about our new parts vendor, Walter Dilley. I recently made a purchase from Walter, Bob, was great especially after many, many purchases. The packaging was outstanding, he was very quick, normally 25 days from the States, was only about 12 days.
I can highly recommend Walter, as an outstanding vendor, professional, friendly, great communicator and very reasonably priced.
I along with other from this group have shared where we buy parts. I purchased from most continents and can say that Walter's service is outstanding and I will keep going back for more when boards\parts are needed
My 2 cents worth including all taxes

and look under how to convert the TS520X. Procedure is essentially the same for the TS830.

Summary: 1. Add another final tube socket,filament supply, control grid parasitic suppressor, cathode bypass capacitors (mirror what you see on final board for the single final tube).
2. Rewire HV supply from 400v bridge to 800v voltage doubler
3. Remove screen grid supply dropping resistor
4. Remove RF drive shunt capacitor C13 at Final board.
5. Add another plate choke parasitic suppressor and anode cap.

Yes that IS a BOAT LOAD of capacitors!!

I mean no disrespect but I continue to wonder why so many hams today get suckered into the idea that all capacitors on the PC boards or in the radio must be replaced because they are old. There are only a few capacitors I would recommend replacing due to age and they are the power supply filter caps. The other various smaller electrolytic, ceramic disc, and mica capacitors on the PC boards that simply do not need replacing!

Replacing ALL capacitors regardless whether the capacitor is good or bad, is referred to as the "Shot Gun" method of component replacement. This method is irresponsible and can easily create problems the radio never initially had. Some of those problems are:

1. Breaks in the PC board foil runs
2. Cracks in the PC foil runs due to excessive heat
3. PC foil runs lifting off the PC board which can lead to breakage and/or poor connection to the foil run
4. Cracks at the PC board plug pin pads causing loss of connection between the circuit and the plug pin
5. Any problems the radio had that may have be caused by a failed capacitor(s), replacing ALL of the capacitors at once, the technician didn't learn anything nor can the technician tell which capacitor(s) that were replaced caused the initial problem!!!

Try tracking down, after every capacitor has been replaced, a broken/cracked PC board foil run or crack in a plug pin pad to foil run that's now caused your precious TS-830S that worked great BEFORE you replaced every capacitor in the radio, to no longer work properly!! It's not the radio's fault but rather the owner who followed the irresponsible shot gun component replacement method!!

Generally, only the paper capacitors qualify for bulk replacement in 40-year-old electronic devices. Although an old paper capacitor may test OK at low voltages, they have a habit of leaking electrically when higher voltages are applied. This turns the capacitor into a resistor, but only at higher voltages. A real bitch to troubleshoot, thus the bulk replacement.

These guys are not replacing inter-stage coupling capacitors which are disc ceramics in the hybrids. They are replacing all the aluminum electrolytic caps. No paper caps in KW hybrids. I have provided my 2 cents on this topic more times than I can count including most recently in message # 53001.

Topic: 53150 Message: 53181

I believe that the majority of these guys are mass replacing all the aluminum electrolytic capacitors under the reliability centered maintenance or life extension umbrella and not a "shot gun" corrective maintenance approach to an operational problem. They have been told by sellers of the kits that an aluminum electrolytic capacitor has a limited life span and all the KW hybrids have long exceeded that life span. While it is certainly true that the radios are long beyond their economic design life, I believe that they have many more operational hours remaining. In my opinion wear out of the electro-mechanical devices is a more serious problem as typically only recourse is installing a "good" used pulled replacement ie pots, switches, pushbuttons, relays etc.

Certainly electrolytic capacitors do have a design life span, but determining that number of hours is not an easy task. It is complicated by a lack of manufacturing standards and definitions. You can see that if you look at the various manufacturers data sheets. Seldom do any two agree.

The question we should be asking is "How long will these capacitors survive in our KW hybrid applications?". When you look at the data sheets you will see a variety of definitions used including Load life, Service life, Useful life, Endurance, Operational life, Life expectancy and so on. These typically are not defined the same way. Most common factor seems to be that all the manufacturers use the "bath tube curve" with its 3 failure zones. Some agree on the definition by showing Life based on Leakage Current Change, Capacity Change, and Dissipation Factor Change.

Some have charts or graphs that predict life hours based on Applied Voltage, Applied Current, and Operating Temperature. Temperature seems to be the most limiting factor. One CDE data sheet showed 7000 hours life based on 105 degrees C (221F) and that same capacitor could expect greater than 200,000 hours life at a temperature of 40 degrees C (104F) with less than 1% failure rate.

If you had an electrolytic in your TS830 that you ran 8 hours per day at 40C the calc would look like this:
200,000/8 = 25,000 days or 25,000/365 = 68.5 years or greater. Of course we have no idea where the operating temperatures of the various electrolytic capacitors are running at. I doubt in the 105C range, but no means to measure. Infrared thermography comes to mind.

All I can go by is outright failures that I see based on number of rigs that cross my bench annually. In my experience with the exception of the HV caps and perhaps the 300/210 caps we dont see any electrolytic filter capacitor failures. The difficult question to answer is.....Are we experiencing performance degradation due to increased Leakage current, change in Capacitance value, or change in Dissipation factor that would warrant total recap? Increased Dissipation Factor means loss in the dielectric at RF frequencies. This results in dielectric heating and if severe enough can cause capacitor failure. Anyone see a cracked RF bypass capacitor at the base of the RF Plate choke? That is dielectric heating.

My answer to degraded performance is that I measure parameters such as receiver MDS and AGC threshold on every model Hybrid and I find them to be in spec or I am able to return them to spec with good cleaning and service manual alignment. I rarely see receiver performance issues that are directly attributable to a degraded electrolytic capacitor.

One thing I do see a lot on most of the technical forums is people being told their problem is most likely due to bad capacitors or someone saying they replaced one or more capacitors and it didnt fix the problem. For some reason "bad capacitor" is commonly high on the root cause "guessing" list.

Until I start to see an increase in electrolytic capacitor failures or someone can provide measureable performance improvement data from a total recap I will continue to only replace the high energy power supply filter caps under the PM umbrella and will not offer my customers complete electrolytic capacitor replacements.

Everything we do is based on risk vs reward and I have yet to be convinced that the rewards are worth the risks associated with this practice. Of course willing to listen to anyone who has a different experience.

Hi Jan:

Thanks. Just one mans opinion based on a little bit of KW hybrid repair experience on old phenolic boards.

I am not saying it cant be done, but it takes some skill, attention to detail, proper de-soldering and soldering tools, and I am afraid some luck. Just want people going down this path to go into it with their eyes wide open.

Take Care

Terry K9TW

53184. TS 830s AGC Fault

Mike:

1. Is RF-1 3.6vdc at cold start? If not clean and exercise VR-3 trim pot and set RF-1.
2. What is RFG voltage at cold start with RF gain pot full CW? It should be same as RF-1 (approx 3.6vdc). If not clean and exercise RF Gain pot.
3. Try tapping on cover of RL-1 aux control relay on the audio board. Suggest in any event that you replace it with a K4EAA replacement board with plug in relays. This relay is cause of many intermittent problems.
4. Wiggle or unplug and replug Molex Connector 9 on IF board to see if have dirty connection at SM pin.

The fact that you see 2 volts on the bus initially indicates item 1 or 2 as the problem.

Item 3 and 4 wont pull the AGC bus/rail voltage down to 2 volts. Should only effect the voltage supplied to the meter movement.

Mike:

If RF-1 and RFG voltages are normal at power on and thru the warm up cycle you might want to ask yourself what loads normal and abnormal does the AGC bus/rail see that would pull the 3.6vdc down and drive the S-meter upscale during a warm up period.

Make sure you measure and monitor RFG at the IF board at Molex connector 8 with RF gain pot full CW and do so from initial power on thru the warm up period as the S-meter is falling back. It should be close to 3.6vdc.

Normal loads include:
1. Off air signals coming in the SO-239 connector.
2. The Marker being turned on and VFO tuned near 25khz step.

Both of these signal sources come down the IF chain and are rectified by the AGC detector diodes which biases on AGC amp Q10 which looks like an electronic rheostat to the AGC bus and pulls the bus voltage down and drives the meter upscale. If you had the Marker on and VFO near 25khz step it would cause S-meter to deflect, but you should hear the marker and be able to adjust the meter deflection by tuning the VFO.

I cant think of any off air signal that would only be there during the warm up period?

3. AGC time constant capacitors on the IF and RF boards present a dead short or low impedance load to the AGC bus at power on and that is the momentary S-meter spike that you see. Even if one or more were leaky I dont think that the leakage would improve over the warm up period.

4. The only other normal loads that the AGC bus sees are all the Gate 2's of all the gain controlled dual gate mosfets on the IF and RF board. Gate 2 of a good mosfet is very high impedance. Have never seen a mosfet with low Z gate that went high Z during warm up.

In my experience a bad or abnormal load causes low AGC bus voltage with its accompanying S-meter deflection and it does not get better over a warm up period. Those abnormal loads most commonly include the meter FET Q11 and the AGC Amp (BJT) Q10. When they fail (short) the S-meter is typically pegged and receiver gain and audio are very weak and these devices dont heal themselves with time.

Hello friends.
I want to know how I get AF signal before the amplifier, so that it is of a constant level, without being affected by the volume potentiometer.
I have the service manual my TS820S, and I've been seeing that maybe from the terminal No. 3 of the volume potentiometer could, but the question I have is whether this would affect the amplifier circuit AF-AVR.
Any suggestion will be welcome.
Best regards from Spain.

The audio level at the TS-820/TS-820S AF AVR Unit plug AF3 pin 2 is not affected (varied) by the front panel AF volume control. I do not know the audio level at AF AVR Unit plug AF3 pin 2. I also do not know what negative affect, if any, would occur by tapping the audio at AF AVR Unit plug AF3 pin 2 for other uses.

Rafa:

The signal level at AF3 Pin 2 AV1 is max of approx 1.5v P-P (Marker on or S9 off air signal). This is based on O-scope measurement with a 1X probe (1 meg input Z). The 2SC1000(GR) pre-amp is rated at a max Ic of 100ma and 200mw dissipation.

It might help if we knew what you want to hang on it. Perhaps someone has used it to drive the same thing that you want to do and can share their experience.

Kevin:

Refer to the Service Manual alignment Steps 15 and Step 21.

When you do the IFT alignment Step 15 you will adjust L9 for maximum gain. Adjustment of L9 will effect AGC threshold.

When you do the S meter cal Step 21 you will go back and re-adjust L9 for a S1 indication with an 8dB signal injected into the SO-239. Need a calibrated RF Sig Gen to do this alignment.

8dB is 1.26uv or -105dBm (more common units on better sig gen output attenuator).

I commonly find that this adjustment is not performed or is performed for max gain only.

Kevin:

I forgot to mention that those who do not have a decent Sig Gen can perform the IFT and S meter cal using the Marker signal as described in the Owners Operating Manual under Maintenance Section 6.

However, you will note that they tell you in bold and caps DO NOT adjust L9 in the IFT adjustment paragraph. They assume that it has been properly set at the factory and remains in that position for an S1 deflection with -105dBm signal.

Unfortunately at this age and the number of hands that most TS830s have seen it is not a safe bet that L9 among other adjustment devices have never been touched. About 50% of the time on the 830s that I see I find L9 to have been adjusted for max S-meter indication and not for S1.

You can kind of tell if you note the position of the L9 core and slowly turn it clockwise and see if you get increased or decreased S-meter indication. If you can obtain significant increase with about 1/4 turn CW rotation it is more likely that the as found core position was close to a factory S1 indication. If you get little increase or S-meter starts down with little clockwise core rotation it means someone has been there before you and set it for max gain and max S meter deflection.

A non precise way to adjust L9 using the Marker would be to adjust the core cw for a max S-meter indication and then turn the core approx 1/4 turn CCW. For example max S meter might be 5 over and then 1/4 turn CCW would result in an S9 indication.

Hi Terry and Group,

I saw those adjustments in the Service manual. The problem is that my RF sig gen does not have a step attenuator. It works OK for many things, but not this. I'm not sure if it warrants the expense considering the limited repairs I do. Some of the units I've seen with a step attenuator were very expensive. I had actually considered trying to hook a step attenuator to a TS-430s that I have and use it, but it's just too nice a radio and I can't bring myself to do it.

If you or anyone else have an idea for a decent RF generator that isn't going to put me into the streets, I'm all ears.

Thank You,
Kevin N2FLP

Wow Terry. That is great info. I wrote my previous post that I didn't have a decent sig gen with step attenuator and sent it just before I saw yours regarding using the Marker gen. I knew I could use the Marker for an S9 setting, but had no way to go with L9. I was in a bit of a jam, but now I can at least get a reasonable adjustment.

They may just be too steep, but I'd still like your input on a decent sig gen.

As always, thank you for the great info.

Hi Terry.
You are right, maybe that's the first thing I should have said.
Well, it's about connecting a decoder CW works with AF, but needs a level slightly elevated audio, which can be annoying if I do not use headphones, and if I use I find an excessive level of audio for me .
Currently it is connected to the output of the phone patch, but this is also controlled by the volume potentiometer.
Although the output level of the connection you want to get is low, it does not matter because I can attack a small AF amplifier and its output connected to the decoder input.
I hope I have explained well what I do.
Best regards.

Well, that is basically what I did with a TS-520 I am working on.

You'll need to make an adapter plate to enable you to get the proper wires out. I ran them out to a terminal strip (solder tie point).

Good luck!

Robert

Why do all that unnecessary hodge-podge electrolytic capacitor connections to replace two aging HV filter capacitors when Ken, K4DAA, sells a complete HV filter capacitor replacement kit, HV-150B, that contains two 120ufd 500VDC filter caps, two .01ufd 1KVDC disc caps, and two 470K 1/2 watt resistors?

Kevin:

Of course cost is a relative term to each person and how they choose to spend their discretionary income. Some think nothing of two packs of cigarettes a day and case of beer but wouldnt think of spending $100.00 on piece of test gear.

Dennis McGrew K8IFF (dmcgrew@comcast.net) refurbs and sells the Wavetek 3002 RF sig gens at around $250.00. I have two of his units as well as HP8640B, but I service these radios and charge people to return their KW hybrids to as close as possible to factory spec so I need something above old LC oscillator sig gen like Heath, Eico, Knight etc.

There is one pretty decent LC type that has a pretty accurate step attenuator and that is a BK E200D. It is solid state and pretty stable. There are several articles on how to improve leakage level and how to add a jack for a frequency counter.

Of course can still find a HP606 or URM25 from time to time. High quality but very big and heavy and getting long in the tooth. Owned them all at one time or another.

The Elecraft XG-3 DDS sig gen has the most common switched RF output levels for testing and alignment and of course you can feed its output into a step attenuator. Its output is a square wave (which isnt a problem) but some folks have added outboard low pass filters to get sine wave. It is pocket size and real handy to carry to hamfests.

You can build step attenuators and/or find them on Ebay. Elecraft and Hendricks QRP and others sell them including kits. Pretty hard to build a good one for price of a kit or just buying outright. I use the HP 355C and 355D units which are a little salty but high quality.

Nothing wrong with "opening up" your more modern KW transceiver and using it as a RF sig gen. It is done all the time. One of nice things is you can have enough RF level to use it as a substitute transmitter driver stage.

OK have to see the manual and schematic to see what the CW Decoders input looks like.

My guess is that the decoders normal input is derived from the rigs external speaker jack or headphone jack. I would think that the Decoders Line Input would have an adjustable attenuator ahead of any IC chip that it may be driving to digitize the CW audio. In that way you should be able to set your rigs AF gain pot for normal comfortable listening and then adjust the Line In gain/attenuator pot for what the Decoder likes to see.

I would connect O-scope to AV1 and watch the P-P level as you temporarily attach CW Decoder input lead to AV1 to see if it pulls it down significantly. Can also place finger on Q2 and should not feel hot.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <lopez@...> wrote :

Hi Terry.
You are right, maybe that's the first thing I should have said.
Well, it's about connecting a decoder CW works with AF, but needs a level slightly elevated audio, which can be annoying if I do not use headphones, and if I use I find an excessive level of audio for me .
Currently it is connected to the output of the phone patch, but this is also controlled by the volume potentiometer.
Although the output level of the connection you want to get is low, it does not matter because I can attack a small AF amplifier and its output connected to the decoder input.
I hope I have explained well what I do.
Best regards.

I forgot to mention that I suspect that many people are using software and feeding rigs audio into computers sound card to decode CW and read it on the PC display today?

I have no experience with this, but if I wanted to decode CW I would look at this method before buying a hardware decoder like MFJ unit etc.

Might have to place a simple pad in series with headphone out to PC sound card line in so dont over drive it but easy thing to do.

Just a comment.

Most sound card interfaces such as the MFJ-1275 have internal pots to control both TX and RX audio levels.

The picture below is a simple and easy to build and use sound card interface. This could easily be used with the CW decorder/display.

I have an MFJ-1275 sound card interface and the internal pots work very well to control the level of audio in both TX and RX. The interface works in RTTY, AMTOR, PSK31, CW, and other sound card TX/RX digital modes. The MFJ-1275 is a bit over kill for decoding various CW, RTTY, AMATOR, PSK31, and other digital modes. One can build their own for a lot less plus they would learn something in the process.

I did build my own sound card and serial TTL to RS-232 / RS-232 to TTL interface, all on one board. The TTL/RS232 section used the inexpensive MAX232 serial TTL/RS232 "dip" chip, not SMT chip. The sound card used Radio Shack inexpensive audio transformers to isolate the TX and RX audio from the computer sound card and PC board pots for controlling TX and RX audio levels. The PTT circuit used an opto isolator available on ebay, Radio Shack, and other electronic parts outlets, connected to a USB/RS-232 cable's RTS and DTR serial control signals for sending CW and activating the transceiver's PTT (VOX could also be used) . These are very easy and inexpensive circuits to build for TX, RX, or simply an RX ONLY audio signal processing unit (CW, RTTY, AMTOR, and PSK31). A simple RX only circuit can be built and connected between the radio and the CW decorder by using only one section of the above schematic.

Didn't mean to change the subject of the thread, just thought I would add my 2 cents about audio interfacing between a transceiver and a computer sound card/CW decoder.

Dave

Thanks. Just wanted to provide the Op with options other than hanging a CW reader on the audio pre-amp output device. He doesnt want to drive his reader off the Phone patch out or tap any other audio out that the level to the CW reader will vary with the AF gain pot setting. I have no idea whose reader he wants to use nor would I know how varying audio input level to the reader would effect its ability for flawless copy. I could see where he would not want to have to adjust audio input levels to the reader every time he adjusted his AF gain pot should that be a requirement.

Easy to obtain constant output level, but no way to know what effect hanging his reader at that point will have on the 820 AF pre-amp.

I hoped others would speak up and provide him with current best practice options other than tapping constant audio out.

Dear John.
Undoubtedly the best CW to decode is the human ear, but also, not everyone has the same ability to learn morse, and although I have some time trying to learn, I still have not managed to do.
Long ago, I bought a Telereader CW decoder, mod. CWR-682, built in 1982, which have been abandoned until recently, and that only serves to CW, I must say it works very well, better than any software I've tried, and that helps me support my reception. It is capable of receiving very unfavorable conditions, even with some QRM, because it has, in addition to an audio filter 40 Hz, a potentiometer for sensitivity, plus integrated wear an electronic keyer.
Anyway, I am still studying and practicing my reception morse for a day to remove the decoder and are my ears which decode these magnificent sounds that are morse signals.
Best regards and hope to hear one day.

I think the "best practice" is to learn the Morse Code.It's really not that difficult....even 5wpm. For persons with hearing difficulty, amplification, filtering, etc. are easy to add after the phone/speaker jack, and are excellent. The human ear and brain are the best CW decoders made so far, they will function where the modern devices have difficulty or fail, as pointed out by a prior post. What happens when the device/keyboard/code reader and/or other associated parts break? But, to each his own....that's what makes this hobby great..and has gotten us to where we are today.

My response was simply to show Rafa, a couple of ways to connect the RX audio to a CW decoder or sound card interface, whether it be audio from a constant level source such as the AF AVR Unit plug AF3 pin 2 that /*does not appear*/ to vary when the front panel volume control is adjusted or from the speaker or Phone Patch out sockets on the rear panel of the TS-820 using a sound card interface's audio input adjustable pot.

I have tried various CW decoding software such as HRD/DM780, MixW, and CWGet using both commercial and home built sound card interfaces as well as firmware based AEA PK-232 terminal unit. I found that none of these methods can beat your EARS to "pick out" what the sender is actually sending.

Software or firmware decoders cannot "think" on their own, they display what the end result decoding table tells them. If the decoded dits and dahs does not correspond to a character in the software or firmware character list then the software or firmware either displays a space, some other silly character, or it doesn't display anything. This happens quite often when characters are not properly formed, character and word spacing is bad, and/or high noise levels and signal fading occurs.

Rafa, having said all that, if you want to use your CW Decoder, that's entirely up to you.

Hi Rafa,

I think the most practical way to answer this
question is to try it. I would take the output of
the preamp (AF3 Pin 2) via a 0.1uf capacitor
directly to your device or to a preamp. You will
hear it right away if the level in the radio is
affected in any way. As Terry suggests, you can
look at the level on pin 2 with a 'scope and you
will also see immediately if there is any effect.

Dondi,

I have a number of capacitor data files that cover a variety of capacitor usage subjects on my website. These files are in pdf format and are from two of the major capacitor manufacturers, CDE and VISHAY.

Click on the link below. When the website comes up click on the /*Manuals and Documents*/ link at the top of the page. When the /*Manuals and Documents */page comes up, scroll down to the "/*Capacitor Data*/" listing and click on the desired file link.

In the International Radio TS-830s User Supplement (1987), N6BV describes a way to improve the skirt selectivity of the IF filters by adding a shield under the IF board. Has anyone tried that and if so, is it worth the effort?

Dondi:

You are not going to see any meaningful increase in power raising the capacitance value of the filter caps. Power capability is primarily limited by the dissipation rating of the tubes and the power transformer.

The primary consideration that KW engineers used in sizing the voltage doubler filter caps was the permissible level of ripple voltage. Like all component sizing there are trade offs on cost, size, weight etc.

There will be a point of diminishing returns on ripple reduction as you go significantly higher in capacitance value. One concern could be if too large a value capacitor is subbed for the original you might result in too high a turn on surge current and could blow primary fuse.

A rough calc for the design capacitance value would be C (in farads) = 0.7 x load current/ P-P ripple x ripple frequency (in this case 120hz).

I would not attempt to measure the ripple voltage on the 900vdc supply with an O-scope unless you have a proper probe like a 100X P5100.

Therer is a xtal for each band that mixes down the PLL oscillator to the IF frequency. There is a separate VCO (voltage controlled oscillator) in the PLL chain for each band. Ther band switch controls all of these as well as some of the fixed digits in the digital display. You can download the service manual. I've just been through a similar issue so I got intimately acquainted with how the TS820 works.

From: lonelyone_64109@...
Topic: 53075 Message: 53230

The saga continues....

Got the coupler and replacement transistor yesterday. After taking out Q7 I noticed that the leg orientation of the replacement transistor did not match the old one (I was assuming the 2SK19 was the correct number as per the service manual, which crossed to a NTE133) . So I did some checking and come to find out the old transistor was a 2SK192A instead of a 2SK19. The schematic is also wrong. Fortunately I happened to have a couple in my parts stash (NTE312 is the cross for the 2SK192). I replaced the transistor and put in a new coupler for the bandswitch (the original was cracked) and fired up the rig.

Now the meter does not peg anymore but the receive is very low. The RF gain does make a little difference but the S meter does not swing from resting (RF gain pot fully CW) to S9+60 dB (RF gain pot fully CCW). I checked the AGC line and now it reads 8.19V. I checked the RFG line on the IF board and it goes from .76 to 3.19 volts (as per the RF gain pot going from CCW to CW). Since the AGC is reading much higher than normal it is probably shutting down the receive and causing the signal strength to be very low.

Haven't had a chance to look further yet.

Seeing that the AGC feeds both the AF and RF boards and that the receive is very low still I am thinking that there is a problem on the RF board (Q1 is fed by the AGC voltage). Can I unplug the AGC from the AF board without causing problems? I tried switching the AGC off and there was no difference in signal level. On my TS520S if I go from AGC slow to fast to off the audio gets quite louder in the off position where it doesn't change on the 530SP.

You need to be methodical about fault finding. Go to the service manual, and follow the block diagram and check the test points. As I have not followed this issue am coming in half baked.
Have you checked the relay on the If board. You mentioned you replaced the nylon coupler, did you make sure s22 was in the correct orientation to the vertical wafer switches? Have you checked for cracked track/traces on the molex connectors. Have you made sure RIF voltages are correct/ in spec.

Sorry if you have under taken these checks, but almost impossible to find fault without being methodical in fault finding.
I am an expert on not following methodical approach in my own personal radios,but clients are always followed by methodical process.

Hi everyone,
I have acquired a TS 830S, all I had to do was to clean some of the switches and swap out the HV caps.
It seems to work fine, audio on tx is awesome and the rx is very lively.
One question, the fan turns over very slowly, it is wired on the 0/100v taps on the transformer and the transformer is locked at the correct setting (240v).
Do these fans turn over slowly or could it be that someone has put in a 240v version which is running far too slowly.
Thanks
Mike

Hi everyone
I have just acquired a TS 830S, I have changed the HV caps, cleaned the switches and a few other small bits but it is now working.
One question, the fan appears to be running very slow compared t the fans on my other kit.
The tcvr is set for the correct voltage (240v it is locked with a plate) and the fan is wired between 0 and 100v taps as per manual.
Is it possible that the fan fitted is a 220/240v one and therefore wired incorrectly.

Hello hybrid fans,
My TS530S had been stored for some time. When fired up it did not start up : hum noise but no signal received, no frequency display. First checks : The band signal (8V) is OK from band switch. PLL board signals are OK : VCO according to bands, VFO, carrier.But the DCBA from counter unit is sticked to 1000 whatever the band. I understand it is produced from diode matrix and 4011 IC Q14.
Any idea?
Thank for your help,
Jean-Louis F5DYD

All of the hybrid fans run very slowly to keep the noise down. If you are concerned, you can remove the fan by removing the screws on each corner of the plastic shroud and very carefully pull it out enough to expose the oil hole. Put a couple of drops of light oil in and check things out.

KW used both the 2SK19 and 2SK192 (GR) interchangeably in the Q7 meter FET location. Just depends on the model year and the rev number of the IF board. This is the same situation with the TS830.

I cautioned you several times about attention to detail when it came to pin out and lead transposition with substitute devices. I believe in my last post I placed the caution in the last sentence so it would jump out at you.

If you now have in excess of 8vdc on the AGC bus then why would you expect to see any AGC action and any corresponding S meter deflection? Normal AGC is fed via RF-1 thru a 2.2 meg series resisitor making it a very high Z power supply. This way it is very sensitive to any loads it sees such as off air signals or marker signal. With 8vdc standing on the bus there is no way for the AGC amp Q6 to pull the bus down when it is biased on by AGC detector diode action.

With 8 vdc on the bus now and normal RF-1 you now have parallelled two power supplies to feed the AGC bus. Normal 3.3vdc High Z power supply is in parallel with a 8vdc low Z supply and no chance in heck for it to offset the 8vdc and provide a variable dc control voltage to Gate 2 of any of the gain controlled devices (RF amp and IF amp dual gate mosfets). Varying the RF gain pot, turning on the Marker or tuning in a strong off air signal wont be able to overcome the standing 8vdc plus control voltage being applied to the gain controlled devices.

With 8vdc standing on the AGC bus your signal to noise ratio should have deteriorated with much higher background noise level and even some distortion in the audio. Should not have resulted in lower signals.

At around 4vdc on Gate 2 the devices are at the knee of the gain curve and turned on pretty hard.

Most likely way that 8vdc is now standing on the AGC bus in parallel with the normal 3.3 vdc is due to a shorted replacement Q7 that is applying the RLR supplied Drain voltage to the Gate or you bridged Drain to Gate solder pads when you installed the sub FET or the sub FET DG leads are making contact where you transposed them (crossed them under the device body) and did not apply any insulating spaghetti to the leads.

I wouldnt worry about Q1 RF amp on RF board until confirmed that you have a good Q7 and restore AGC bus to 3.3vdc. Of course you can unplug Conn 5 on RF board and remove AGC control voltage to Q1, but you will lose all receive as you will lose Q1 and RIF out to the IF board.

I have given you all the help that I can on this subject. Dave VK5PDL is a good TS530 tech who can help you from this point forward.

Jean,

You said when you powered up your TS-530 after being stored for some time, you saw "no digital display". Loss of digital display is an indication the PLL Unit has changed to the "UNLOCK" state. When the PLL Unit changes to the UNLOCK state and if this occurs on all bands then each bands VCO is "disabled". This results in loss of the VCO signal at the RF Unit's "VCO terminal" causing loss of both receive and transmit.

An UNLOCK PLL Unit can be caused, for example, by loss of the 8Mhz CAR Unit or VFO Unit signals to the PLL Unit or a failure in the PLL system itself due to corrosion on the PLL Unit board's pins and/or bad grounds on the PLL Unit PC board itself (board's mounting screws).

The TS-530 service manual, page 4 Fig 1, shows the block diagram of the PLL system and discusses how the TS-530 PLL Unit works to control both TX and RX.

Mike, a common problem with the 30 series. It could be as simple as the noise blanker adjustment pot on front panel being adjusted too high. If it is near full cw, try backing off to about 3 o'clock position.

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by Jimmy, WB2KNR.
There were 14 stations checking in under bad band
conditions. He was contending with QSO party
splatter. There were 2 first time check-ins, WA4GZE, W1LGU and KB8NME

We had the following number of radios checking in.

3 running TS-520(x)
0 running TS-530(x)
1 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

He was running a TS-520 with a Heath SB-200.

The Sunday net was run by me, WB0IQK. There were
11 stations checking in under fair good
conditions. We had the following number of radios checking in.

2 running TS-520(x)
2 running TS-530(x)
2 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running a TS-520S with my L-4B AMP.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:

Hi gang,

Ok so I'm putting back together my 820s and when I got to the IF board connectors I'm not sure which one of the 3 pin with the grey and shield wire if it goes to pins 1 and 2 or 234 on the 17 pin header. My schematics are hard to read and I broke Google looking for photos of the connectors.

Thanks all
Rory

Hi Dave

I had already tried that "hi" but these things usually are a simple case of finger trouble.

Actually it was R12 (the 1M) on the RF unit, I changed it to a 47K as per survival guide.

It was a pig as one end of the old resistor was clipped short but I managed to do as the guide suggested and connect the new R to the two leads.

There were no strong signals on 40m but I switched it to the 1.5 mhz range stuck the G5RV (which is full size and at 50 ft) into the antenna socket and tuned to 1.548, a local station which is multiple kilowatt and only 2 miles away.

It sounded sweet so fingers crossed.

The only nasty I have found is a little play on the vfo shaft, same problem as I had on my Drake TR7, I changed the bearings to solve it but on the Trio I have improved it by fitting a new spring behind the VFO knob.

Thanks

Regards

Mike

Rory,

I could be wrong but it appears you may be referring to the IF Unit 3 wire plug, IF2.

Position "A" selects the SSB filter in ALL modes (this position is used if the CW filter is not installed). GREEN wire to pin 1, PURPLE wire to pin 2 and GRAY wire to pin 3.

Position "B" selects the SSB filter in USB/LSB and selects the CW filter in TUNE/CW and FSK (FSK 170Hz shift). GREEN wire to pin 3, PURPLE wire to pin 4, and GRAY wire to pin 5 (CW filter must be installed for TUNE/CW modes). Transmitter TUNE MODE ALC peak adjustment requires the CW filter to be installed in this position.

Position "C" selects the SSB filter in USB/LSB/FSK (FSK 850Hz shift) but selects the CW filter in TUNE/CW modes. GREEN wire to pin 2, PURPLE wire to pin 3, and GRAY wire to pin 4 (CW filter must be installed for TUNE/CW modes). Transmitter TUNE MODE ALC peak adjustment requires the CW filter to be installed in this position.

MODE switch wafer S6-1 setting and the position of IF2 plug on the IF Unit determines which filter is selected by applying +14VDC from the AF AVR Unit plug AF1 pin 3 (14) through MODE switch wafer S6-1 to the appropriate filter select diodes on the IF Unit. Diodes D5 and D6 select the SSB filter and diodes D7 and D8 select the CW filter.

Note, if the CW filter is not installed, neither TUNE or CW modes will work.

Hi Dave:

One additional thought is I would be very cautious performing any of the mods contained in the 830 "Survival Guide". Before doing any I would come here and ask the experience and opinion of our members.The vast majority of these items are not KW factory developed, approved, and issued under the Service Bulletin umbrella.

These for the most part are just a collection of anecdotal input from early owners of factory new KW hybrids. Many of the described mods were pulled directly from the TK Newsletters that Rob Pohorence N8RT owner of International Radio published for the International Radio Users Radio Club members. Almost all were submitted to the TK Newsletters in the early 80s when the 1 Million series radios were getting in the hands of new owners and as many hams of that era did modifications to brand new radios abounded. Some of which were ill conceived. Very few if any of these mods were ever picked up by KW and integrated into later model year production runs.

In the case of Skirt Selectivity January 83 Issue #30 proposed a shield installation to provide better isolation between IF filter input and output (filter blowby) and in the case of AGC action in the presence of strong signals June 1983 Issue #35 proposes several changes to AGC RC time constant components.

I understand that modification is the essence of the hobby for some including design changes to factory new radios. In a few cases these changes are in fact picked up by the manufacturer, but that is not the norm with our Hybrids.

I understand that some owners live in metropolitan areas and their antennas see very strong signals from high power Shortwave and AM stations which can overload the front end. KW understood that as well. Before messing with AGC time constants and changing attack times at the RF amp I would have done couple of things in addition to asking for opinions here:
1. KW provides the RF attenuator switch. What effect did it have on the offending 40 meter signals?
2. Are you aware that there is an "automatic" RF attenuator circuit? It is not common for it to fail. KW with the introduction of the TS520S and 160 coverage added a diode switched capacitive voltage divider shunt attenuator between the RF amp and RF mixer. I have discussed its operation several times here in the past in the TS820 as well as the TS830 radios. Essentially, the diode switching bias is provided by the bandswitch diode matrix and a portion of the RF signal at the output of the RF amp is shunted to ground on 160 thru 15 meters and full gain is provided on 10 and 12 meters (24-28-29).The combination of the manual switched RF gain attenuator and the "auto" attenuator should work in most strong signal situations. If not familiar with the "auto" circuit read its description in the TS520S service manual and look at the TS830 circuitry on the RF board in the area of D3 diode between the RF amp and FET buffer ahead of the RIF Mixer.
3. We have an RF gain control pot and leaving it in full CW position is not required. I suspect there are some old timers that routinely ride the pot. With 1500 watts the norm on 40 and 80 meter nets I often dial it back and never hear "offending" weak signals as I copy the Net.

I am pretty confident that KW engineers were fully aware that the SO-239 connectors of their Hybrids would be subject to a wide range of input signal levels. To address that they had an AGC gain adjustment objective to prevent overload and/or IMD production and lastly to present signal levels to the Product Detector that would not result in "rough" sounding audio. This is no easy task to accomplish and it requires that AGC time constants between the RF and IF stage be deliberately staggered to prevent loop instability. This can be especially challenging when strong signals are present at the steep filter skirts and filter delay has to be considered along with AGC time constant delays.

To that end it is true that KW did play around with AGC time constant RC components especially on the TS830 model and depending on what model year and what Rev IF and RF boards are in your TS830 (may not even be the factory issued boards) you may find RC components at Q1, Q4 and Q8 as well as at the input to the AGC bus supply on the IF board (C177, C184, C83 etc) that are different than what is called out on the schematic. By about the 6 Million series rigs they had settled on RC values that took into consideration filter skirts selectivity and filter delay and provided intentional RC time constant stagger to ensure AGC loop stability. The final solution that I am aware of was to provide approx 47msec attack delay at Q1 RF amp. By changing 1 meg resistor to 47k you have reduced that delay to approx 2msec. That is a big change. I would be interested to see what you may have done to 10 meter weak signal copy having made this change to RF amp AGC attack time?

As mentioned modification is the essence of the hobby for many. Unfortunately I see many ill conceived and worse yet very poorly executed modifications in the rigs that come across my bench. I spend a lot of time in discovery and removal of these mods per customer approval. I am not saying that is the case here as I have no way of knowing if G3ZCC is dealing with 1 volt across his SO-239 or not. In my experience that would be unusual and certainly more common on 160 meters than 40 meters at least here in the States.

Just want folks to think before they jump for a "Survival Guide " mod. The mod may be ill conceived (wrong cause and effect) and/or it may not be appropriate for your operational issue. Of course it is your rig, but as Dave VK5PDL cautions it is very easy to damage these old phenolic boards.

Sorry so long.

Terry K9TW

Ok Terry,
Tnx for the return.
Yes it is nice to hear another opnion. I had classes on valves at school (high school, vocational) where it leaves electronic technician, so in 1977 ... old time, good times, hi ... I wondered what you talked about (minus the outbreak of off / on).
Well, my English language is not good, so I prefer to believe that I got it wrong when someone spoke (here on ist) that there would be an increase of potecia ...

Well thanks for the help ... we will raise this giant to put it in the air again.

Update, just been listening to the USA on SSB 40 metres W1 to W5 readable, condx not too good.
I2VRN in Milan with 800w to a monobander at 100 feet was crashing through and no crossmod, nice readable signal.
Looks like it is ready to go back into it's case, might just change the fan as it does not seem to have enough airflow for my liking.

Mike,

These rigs were a big success globally and I'm
pretty sure the Kenwood engineers knew what they
were doing when they specified the cooling fan
for the PA. I'm sure if you searched through this
whole list you will not find a single instance of
PA failure due to airflow. There's no good
technical reason for replacing the fan.

Attachments: 1 described; binary payloads are missing from this source WARC

The fans on the rear of the KW hybrids are not designed to blow high volumes of air as one might expect. The fan is not designed so the transceiver can be operated at 100% duty cycle either. The fan simply moves air through the final amp and cabinet vents.

The fan should be checked periodically for dust accumulation on the fan blades. Dust accumulation on the fan blades should be cleaned to prevent slowing of the fan blades which results in reduction in air flow through the final amp and cabinet vents.

The KW hybrid transceiver should not be push back close against a wall nor have other equipment stacked close along each side and on top of the transceiver. Doing so can easily block the air flow through the final amp and cabinet vents.

All of the KW hybrid fans operate off the 0/100VAC secondary winding of the power transformer, regardless of the primary power selected (120VAC or 220VAC). This can be easily seen by viewing the transceiver's main schematic.

The fan socket is the /*small square socket with 2 holes*/ directly below the 120/220V primary power switch, as shown in the above KW hybrid's schematic section.

Hi Lou:

You are of course and as usual 100% correct.

These rigs use RF speech processing and when using it no one likes to hear a "hurricane". The fan is run on 100vac to provide sufficient air movement while not producing noise level that would be heard when using the Speech Processing. We have all heard it. This is an old and repeat subject on this forum which I have found no amount of logic or science will prevail.

Go to WB4HFN website and go to the Kenwood Pages and search under Articles and Info and you will find the TS-820S Technical Specification document. Go to page 10 (page is out of order) and read around the next to last paragraph of the Speech Processing technical discussion. It clearly tells why the fan is speced as it is. People who replace any of the KW hybrid fans with higher speed or higher volume fans are defeating a design parameter for no gain in RF output or 6146 final tube life.

The plate or anode of the 6146 cooling is accomplished primarily by black body (infrared) radiation. No amount of high volume fan blowing on or around the glass envelope will provide any additional plate dissipation.

http://www.wb4hfn.com/KENWOOD/Articles/TS-820-TechInfo3.pdf
http://www.wb4hfn.com/KENWOOD/Articles/TS-820-TechInfo3.pdf

It is however their rig and if they want to put barking dogs, crying babies, and hurricane fan noise on the air it is their choice. Hopefully someone would give them an honest assessment of their poor quality signal.

Terry,
Never saw those two pages were out of order.
Hum. I'll correct it and post an updated copy. Thank's for noting that.

Gerrit, PA1MT

I use a TS-830 on 40M and 20M CW.
(1) I use my own design of an Analog CW Signal Processor , called the "AFX", which is plugged into the TS-830 earphone jack. Near DSP filtering, with Limiting. (2) There is a commercial (simplified versiion available) called a "CALF" from KC9ON.Com,
for around $40, as a kit, and it also works great. The CALF has a very effective limiter and up to six stages of filtering. The kit is user-modifiable for preferences in filtering characteristics, during construction, with six selectable filter settings from 700Hz down to 70Hz.
(3) Information on the "AFX" is at www.GeoCities.WS/glene77is
http://www.GeoCities.WS/glene77is
and the "CALF" kit is for sale at KC9ON.com .
And, you can post on this group, or the Yahoo HW8 Group.

Will be glad to discuss these things.
I operate CW only, am an engineer, and designing filters is my great fun !

Hello Mike,
Thanks for your indications. PLL unit fault was my first diagnosis. But the signals on it (CAR, VCO, VFO, band signal (8V)) are OK. I tried to exchange with a spare with no result.Then I found the DCBA signal from the counter unit to be permanently at 1000 whatever the band selected. The generation of this BCD looks simple with only diod matrix and Q14. The band signal at the input of the counter unit is correct. The BCD output is not.

Mike W5RKL On 10/18/2015 1:57 PM, Mike W5RKL w5rkl@... [TS-520_820_530_830] wrote:

  Jean,

You said when you powered up your TS-530 after being stored for some time, you saw "no digital display". Loss of digital display is an indication the PLL Unit has changed to the "UNLOCK" state. When the PLL Unit changes to the UNLOCK state and if this occurs on all bands then each bands VCO is "disabled". This results in loss of the VCO signal at the RF Unit's "VCO terminal" causing loss of both receive and transmit.

An UNLOCK PLL Unit can be caused, for example, by loss of the 8Mhz CAR Unit or VFO Unit signals to the PLL Unit or a failure in the PLL system itself due to corrosion on the PLL Unit board's pins and/or bad grounds on the PLL Unit PC board itself (board's mounting screws).

The TS-530 service manual, page 4 Fig 1, shows the block diagram of the PLL system and discusses how the TS-530 PLL Unit works to control both TX and RX.

From: Mike Davidsohn
Topic: 53233 Message: 53261

Ok Guys thanks, it was just a question as most of my boat anchors even a TR7 have faster fans.

I am quite happy for a quiet one for a change.

The 830 is in the shack and got a fabulous across the pond qso on 40m SSB 5/9+ both ways so I am delighted with that.

Very happy with the receive too, cant check it on 10m as I don't use bands above 20m.

One thing I did do was to change the 100pf coupling cap to the 6146's for a shiny new one 2KV wkg and only slightly bigger than the original one.

I do this to all my Yaesu rigs as a matter of course, these can and do go leaky and I have seen the results of them failing.

At least my pa's are protected now for the life of the rig.

I can now relax and enjoy an excellent rig.

Thanks for all the tips and suggestions.

Mike

No harm in changing C1 RF drive coupling cap, but not needed and certainly no need for 2kv rating. There is a reason KW speced it at 500wvdc.

This is a late model Kenwood radio and not a Yaesu FT-101 radio.

KW TS830 design is different and doesnt rely on a single failure component to supply RF drive to the finals.

Your TS830 as designed doesnt experience applying Driver tube plate voltage to the control grids of the 6146 finals and destroying them. This is because they also have a C29 .01uf "block" cap in series with C1 coupling cap. C29 is located on the RF board.

"USEFUL" is a relative term. Again will repeat my caveat about owner devised and installed mods. About 90% of the published results are not based on measurement and some are just flat wrong.

Like all News Letters Rob needed input from subscribers each month and very hard for him to screen all of them for technical accuracy. Lots of errors abound in these newsletter articles. Some are pretty innocuous like a new 1 Million series TS830 review that states that the front panel is "Plastic". It is of course diecast zinc and not plastic.

In that same technical review it is stated that during loading of the radio Popping Noises and HV Arcing sounds could be heard and that according to a note in the Owners Operating Instruction Manual these sounds are coming from the 6146B finals and it is normal! This is absurd. If KW ever put such a note in the manual I have never seen it and if they did then shame on them.

Never want to hear any popping or arcing sounds emanating from the PA cage. From time to time you may hear a high pitched "tink" from the PA cage as the final tubes glass envelopes are heating up. A pop today means tube arc over and likely have lost the cathode resistors. Arcing or frying can be due to HV dc or RF. If you hear that you need to shut down the rig and remove PA cage cover and carefully observe another loading attempt to see if you can observe the source of the arcing. It could be coming from the plates of the Plate Load capacitor or less commonly from the Plates of the Plate Tuning capacitor. Or it could be 900vdc tracking in area of the terminal strip or RF Plate chokes. Or it may be coming from the HV rectifier board and not inside the PA Cage. Just have to be very careful not to make any hand contact on any of the energized components. There is over 500 volts RF across the Plate tank cap at 100 watts output and that might not kill you but would sure burn like crazy. And of course contact with the 900vdc anode supply can kill you.

There are other "Useful" tips like telling owners who believe they have weak receiver gain on 10 meters to adjust IF transformer L9 on IF board for maximum gain. This is flat wrong. There is no shortage of gain on 10 meters on a fully functional and well aligned TS830. The proper way to adjust L9 is to adjust for an S1 indication on 14.175 with -105dBm signal injected. Proper adjustment is described in the service manual under the S meter calibration steps. Today if you suspect low receiver gain on any band you would want to perform a coil pack and IFT alignment and then if still low (based on injecting accurate low level into the SO-239) then first place to look is dirty/high resistance bandswitch contacts. Have to determine if low on all bands or just one or two bands. Root cause can be different.

Again I repeat my suggestion that before you perform any of these IR newsletter mods or adjustments you need to make sure that they make sense technically and if you dont have the background to do that then at minimum come hear and ask the members what their experience is. Remember results are often self-fulfilling or feel good and not based on any accurate measurements.

I could continue but you get the idea. Rob is smart man and a good man, but he wasnt able to edit all of these newsletter submittals for technical accuracy. Remember also back then it was pretty common place to buy a new TS830 and take it home and remove the KW filters and install the Fox Tango filters. I cant imagine doing that then on a $1500 radio or today on a $5000 radio. Of course I couldnt afford it either!

Dont want to stick my nose in so will only offer couple of quick items and then move on.

Q14 seldoms fails. Have you measured Pin 14 to ensure you have approx 5.6vdc?

Also would clean the contacts on RF board bandswitch deck S1-1. Easy to access with artist brush and few drops of Deoxit D5.

I think you are saying that DCBA output from Counter Unit to the PLL board is stuck on 1000 in any of the bandswitch positions? I think you said you swapped out the PLL Board? or Did you mean you swapped out the Counter Unit board?

I assume you have measured the diode bias switching voltage (approx 8.9vdc) at the pins on Conn 3 as you switch the bandswitch? Dont just measure them at Conn 4.

You can also measure the input voltage to the 4 gate pairs. It should be approx 4.4vdc.

That about all I can offer.

I forgot to mention if you have 1000 DCBA input to the PLL board did you check to see if you have approx 1v rms VCO signal level output from the PLL Board on 1.5 and 29.5 bandswitch positions?

I would measure the VCO level at TP-3 on the RF board. If no VCO on either of those two bands make sure you have approx 200mv rms VFO input signal level at PLL board Conn 6. I believe you said you verified that you had 300mv of CAR oscillator? Also, make sure you have 1 mhz clock at TP-2 on PLL board.

Even if the Counter Unit only has DCBA output of 1000, Should have operational rig on 1.5 and 29.5 bands.

Hi Terry

I have owned a few Trio's from yesteryear, JR60U, JR500SE, TS 430S and I still use a 9R59D in the workshop as a monitor.

There is no doubt about the build quality of the 830 over the FT101.

An ex Yaesu engineer in a recent magazine article added a 0.01 in series with the coupler to safeguard the PA's.

Looks like Trio already did that.

Very impressed thus far.

I want to connect it to my tube linear (2x572B), if I read the schematic correctly the main relay has two sets of contacts, one n/o and the other n/c going to one of the din sockets on the rear of the transceiver.

That being the case it should be possible to use the n/o to key the linear, it runs happily with my all solid state TR7 and it only needs 60/70w of drive to reach full output.

Mike

KW did it with introduction of the TS820. Not sure what the driver was. Perhaps they learned from Yaesu experience? Important thing is that they did it.

I use to work on FT-101 rigs, but quit as far too many were in hands of CBers and either hacked or modded or abused. It is my opinion that the KWs are better design and better build quality. I have seen a couple of FT-101ZD units and they appear to be a cut above, but know nothing about what operational history has revealed.

Have fun with your KW rigs.

53269. Connecting tube linear to TS-830S remote socket

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-10-22 09:35:52 UTC
From: mike@...
Topic: 53269 Message: 53269

Seems to be some conflicting info, if I read correctly I can connect the control line from the linear directly to the remote socket as the required pins go directly to a relay.
Pin 2 is to be earthed to the chassis connection and the braid from the control lead.
Pin 4 is a n/o connection of that relay which closes on tx to allow the keying of the linear.
There are no connections to the transceiver from those pins other than to the relay.

Thanks
Mike

From: Mike W5RKL
Topic: 53269 Message: 53270

Connecting an amplifier's relay to the TS-830 is very simple. The amplifier's relay connection is connected to the TS-830's REMOTE DIN socket, pins "2" and "4". Pins "2" and "4" act as a simple SPST switch. When the TS-830 switches to transmit, pins "2" and "4" short together, completing the circuit for the amplifier's relay, energizing the amplifier's relay. Switching back to receive, pin 2 and 4 are no longer shorted together causing the amplifier's relay to no longer be energized. Very simple switch circuit.

The ALC connection between the TS-830 REMOTE DIN socket pin 6 "RAL" (Remote ALc) to the amplifier's ALC socket requires a simple connection between the amplifier's ALC socket "center" terminal and pin 6 on the TS-830 REMOTE DIN socket. The coax braid between the TS-830 SO-239 antenna connector and the amplifier's INPUT SO-239 coax connector provides the GROUND/RETURN path for the ALC circuit. The TS-830's REMOTE DIN socket ground AND the SO-239 ground (threaded portion of the SO-239) are at the SAME ground potential.

Date: 2015-10-23 04:21:38 UTC
From: christopher_trouten@...
Topic: 53273 Message: 53273

I found a TS-520S the other day and I've been wanting one for quite a while that would make a good candidate for restoration and this one fits that need perfectly. I paid $60 for it and the seller and I had a nice little conversation in the McDonalds parking lot about how we were hopeful that I would be able to bring the rig back to life and on the air because it had belonged to his father. He said that he was unable to get it to receive any signals alongside his Icom that was pulling them in just fine.

Anyway, I brought it home and opened it up to look for and obvious internal damage and found nothing that alerted me so I decided to power it up and put it through the tune-up procedure to see what would happen. An hour or so and several QSOs later I was smitten by this old, cosmetically abused but fully operational rig! I read about 125 watts output on 20 meters so I won't be needing to replace the finals or driver any time soon. The only real operational issue that I have found is the VFO is not running as smoothly as it should and gets a little crackly in the 200-600 range so it needs a good cleaning and lube. The panel lights are out too but no big deal there.

The biggest issue with this rig is the obvious cosmetic abuse that it has suffered. There's lots of surface rust and the top cover is beat up pretty good. The screws have been overtorqued over the years, causing the screw holes in the cover to become a bit sunken in. The edges of the sheet metal have been bent a little here and there too. All of this can be easily fixed with some care and attention to detail along with some elbow grease and a few coats of the right primer and paint.

The biggest hurdle that I see right now is the face plate. It is in slightly better condition than the top cover but it seems to be made from aluminum. I can't tell if the finish is some type of anodizing or a spray on paint type finish. Either way, how do I refinish it to look factory new? Is there a source for replacement lettering (decals or something) for all of the controls or do I have to find some kind of stencil? I'm really at a loss here. I'd even be willing to either buy a like-new faceplate or pay a reasonable price to have this one professionally restored. Has anybody here ever faced and tackled this problem?

The AC line interference/suppression caps may be leaky. You can lift one side of C23 and C24 one at a time to see if 24vac then goes close to zero.

If so, you can run with them lifted or if you want to return the rig to design config you can replace them with modern UL approved X1/Y2 AC rated "safety caps".

You may be able to find these on Ebay. Also can buy from Mouser or Allied or Newark, but I buy mine from Just Radios. Dave provides good fast service.

Hello Chris,

This is Walter Dilley, kd7dny. I have the Hybrid Inventory of parts (that I purchased from Bob Mansker who had supplied parts for our Kenwood Hybrids). I should have a face plate for your unit available for purchase. If you are interested, send me a picture of your radio to ensure I have the exact one you need (there may be a variant of the 520S that has 160m). Please contact me off-list at
walter.dilley@...

Thanks,
Walter.

These are not electrolytic capacitors. These are AC rated disc ceramic. I dont know of any recap kits that include disc ceramics?

Suggest you search on Conversations on this forum regards electrolytic recapping to read the discussions on risk vs reward.

Some clarification...

If your chassis is properly grounded, you cannot have AC on the chassis.

What if it is not properly grounded?

Each line – “hot” and neutral, is bypassed to the chassis. The two caps provide a voltage divider, with the chassis at the mid point. If the caps are large enough, the chassis will be at half line voltage. If the are not “large enough”, the chassis will be at something less than half line voltage.

I think the only problem you have is that the chassis is not grounded.

Since it's usually brings up a debate/question, I want to be sure I'm clear on what your saying. 'same page' Are you saying an RF ground at the antenna or a 'house ground' or running a separate grounding strap from the TS-520s to an earth ground (copper stack in the ground separate from my house grounding system. I am assuming (dangerous) you are not referring to RF ground at antenna because the voltage is present even when not transmitting. My understanding has been since the 520s never had a 3 pin plug it should not be 'house electrical system' grounded and has never been setup that way. Lewis

Any piece of electrical equipment needs an earth ground – usually provided by the three prong plug.
The bypass capacitors on the AC lines will elevate the chassis above ground unless the chassis is
grounded. (A moderate resistance to ground would probably also pull the chassis voltage down.)
I have been “buzzed” by an ungrounded chassis before.

I have a TS-830, which has a stud on the back with a wing-nut that is supposed to be connected to
an earth ground. Mine is connected to a water pipe that goes into the ground – it could also be
connected to the electrical ground. But it needs to be connected to earth ground in some way.

I agree that all Hybrids should have a earth safety ground connected to the chassis ground stud on rear panel. I should have reminded Op about that. I have equipment ground bus in the shack that is connected to copper water pipe that then is grounded to utility neutral and a sprinkling water well pipe.

However, I dont yet agree that nothing is wrong with the caps.

The reported 24vac from chassis to neutral is very unusual. Normal would be approx 50-55vac regardless of how the line cord plug is plugged in. Before connecting the safety ground to the ground stud would like to see measurements repeated. Plug line cord in and measure and then reverse the line cord and repeat the measurement. If there is 24vac one way I would expect to see approx 75vac with line cord reversed (the 2 wire plug is not polarized on a factory plug and line cord assembly).

If the voltage is not nearly equal then Xc cant be equal and I would change out the caps. These caps see most severe duty in the radio with many years of continuous duty and it is more than a shock hazard. Failure can also be a fire hazard.

I agree that the TS-520's chassis should be solidly bonded (with a jumper wire) to a good AC (system) ground point. Assuming that such a bonding jumper was not present when the original 24 VAC-to-ground was measured, I don't think that the measured voltage (24 VAC) was necessarily indicative of a bad capacitor. The original poster indicated that the 24 VAC was measured with a "DMM". My understanding (maybe wrong) is that most DMM's have a 1 megohm input resistance/impedance. The TS-520 has two line capacitors connected to ground; each is 470 pf. Impedance (capacitive) of a 470 pf capacitor at 60 hz is about 5.6 megohms. So the impedance of the DMM (if 1 megohm, therefore being much less that the impedance of either of the 470 pf capacitors) would "load down" the measurement, and 24 VAC sounds "about right" to me. Measurement of chassis-to-ground voltage of half the line voltage would be observed only if the voltmeter's impedance was significantly higher than the impedance of the capacitor(s). I expect that the observed measurement (of 24 VAC, without an AC bonding jumper) would be the case even if the line cord is reversed. But of course, connecting up (bonding) the radio's chassis to the AC system ground (most easily done by connecting up to the the ground terminal of a three wire outlet) will take care of the problem, and (in my opinion) is recommended for safety's sake.

I have come across recommendations by others that radios such as the KW hybrids which have 2-prong plugs should not be converted to a 3-prong (NEMA 5-15P) plug/cordset. I personally believe a conversion to a 3-prong plug is worthwhile from a safety standpoint. Although it is difficult (physically) to accomplish, and it must be done carefully (the person doing the wiring must ensure that the switched lead is in the "hot" wire and not the neutral). However, running a bonding jumper from the radio's chassis to an AC ground point has the same effect (from a safety standpoint) as rewiring the radio to utilize a 3-prong cord/plug.

That crossed my mind Mike. Be very careful mixing the earth lug (or chassis) on your rig with the house earth. One problem is that you could have a Neutral-Earth fault condition where mains goes through the earth on your rig. And the fault condition need not be in your own house, but could be in another house, depending on which version of neutral-earth wiring your neighbourhood used when it was built.

If the CW filter is installed, the MODE switch is set to CW or TUNE, and the NAR/WIDE switch is set to NAR, the audio heard in the link is what you would hear when attempting to tune a side band signal.

I recommend changing the MODE switch to USB or LSB, depending on the band (LSB for 160, 80, and 40 meters, USB for 20, 15 and 10 meters), and adjust the VFO tuning for a side band signal.

Update: 24v ac, reversed pins 36v AC I also did as suggested and connected chassis ground to house electrical ground.
Is this sufficient?
I was able to make a 15M contact today. One entry in CQ WW DX contest.

So is it safer to connect chassis to house gnd (ie gnd pin on an outet) or run a copper line outside and bond with the house lug there, or run outside and hammer in another ground rod just for the radio? I do have a second ground rod in the ground that the TV antenna is connected to.

To ab9ms@...:

I recommend that you provide a bonding jumper from the TS-520x chassis to the ground lug of a three-wire AC power outlet; this should (I think) reduce the 24 VAC measured radio-chassis-to-ground voltage to near zero and provide some measure of protection (essentially, fault detection leading to tripping of a breaker, or blowing of a panelboard fuse in the event of a 120 VAC fault-to-chassis within the TS-520x) at the panelboard source. [Note: this is for US facilities (residential, commercial, industrial) which are in general conformance with the National Electrical Code; I am ignorant of the design standards for European or other areas.] Additional bonding/grounding jumper(s) from the TS-520x chassis to RF ground(s) (ground rod(s), or otherwise, such as the "second ground rod in the ground that the TV antenna is connected to...") may provide some effect on received and transmitted signal strength.

The bonding jumper from TS-520x to AC power ground is associated with safety (fault detection, and breaker tripping or fuse "blowing") of the AC power system in the event of inadvertent grounding (shorts or "faults") of the 120 VAC wiring to chassis within the TS-520x. This is something that I recommend you do first. The additional ground/bonding connections to "other" ground rods or supposedly grounded points (such as copper water piping) might serve to improve, or worsen (or have no effect on) received and transmitted signals; I recommend that you try them out and see.

Dominic, you should get the service manual, they re available for download on the internet. This shows you how to do an IF alignment if you have a good signal generator . The actual filters are not adjustabloe, you need to get the IF signal back on the right frequencies.I assume you have the right filter in place already and have tried the IF shift and other basic operating controls adjusted to try to get the signals in more clearly.Good luck. Hi Gents.

I wonder if anybody can help.

I have a TS 530/SP, the problem is there is only about 20ma of drive indicated on "ALC" position
on the meter regardless of the positiion of the carrier control.
I replaced the 12BY7A and 6146Bs for known good items from my TS 530s with no effect.
Tuning to a dummy load in CW mode with a watt meter shows about 20watts output for "IP" current of approx 115ma, with the bias set to 50ma.

The meter readings are the same on all bands.

Works fine on receive.

HT Capacitors have been replaced

Best regards

Brian Arnott (G3YYT)

Oggetto: Re: [TS-520_820_530_830] Re: TS-520 NO SIGNAL CURRENT IP IN TUNE MODE

It's easy to verify the presence or loss of 6146 screen voltage on pin 3 of either 6146 tube socket.

Connect a DC volt meter set to measure +200VDC or higher, RED meter probe to pin 3 of either 6146 tube socket and BLACK meter probe to the chassis. Place the MODE switch to CW or either side band modes, the approximate DC voltage should be +255VDC. Leave the meter connected to pin 3 and chassis but change the MODE switch to TUNE. The DC voltage on the meter should decrease by approximately 50%. It is NOT necessary nor required to key the transmitter when measuring the above voltages on the 6146 tube sockets.

If the DC voltage on pin 3 of either 6146 tube socket is in fact found to be 0VDC then check for an open R6 on the HV Unit. If R6 is found to be open or a very high resistance, replace both R5 and R6 resistors on the HV Unit. Don't rely on R5 to be okay to keep, replace both resistors.

HV Unit resistors R5 and R6 form a series resistive voltage divider. The Rectifier Unit's "210A" approximate DC voltage applied to the HV Unit's "210" terminal is +255VDC. With +255VDC applied to the HV Unit's "210" terminal, a total current of 2ma flows through the series resistive circuit.

You can calculate the approximate 6146 pin 3 screen voltage in TUNE Mode by performing simple Ohms Law formula math using a simple calculator (Windows calculator works fine).

First, calculate the total resistance of R5 and R6 voltage divider series circuit which is 112000 ohms (56000 x 2 = 112000). Series resistance simply adds.

Next, calculate the total current flowing in the series circuit which is approximately 2ma and using the Ohms Law formula:

I = E / R

"E" is the +255VDC HV Unit's "210" terminal DC voltage applied to the series voltage divider
"R" is the total resistance of the series circuit (56000 x 2 = 112000)

255 / 112000 = .002

The same 2ma flows through both resistors R5 and R6.

With +255VDC applied to the HV Unit's "210" terminal and 2ma of current flowing R6, a voltage drop of approximately +112VDC will occur across R6. You can calculate this using Ohms Law formula:

E = I x R

"I" is the 2ma of current
"R" is R6's 56K resistance

.002 x 56000 = 112

To calculate the approximate DC voltage at the HV Unit's "TUNE" terminal, you simply subtract +112VDC from +255VDC which should result in an approximate DC voltage of +143VDC found on the HV Unit's "TUNE" terminal and pin 3 of the 6146 tube sockets.

255 - 112 = 143

The above DC voltages, R5 and R6 resistance values can be different due to age of R5 and R6 resistors and the actual DC voltage applied to the HV Unit's "210" terminal.

If R6 is found open then there will be zero volts on the HV Unit's "TUNE" terminal resulting in zero volts on pin 3 of each 6146 tube socket resulting in an IP meter indication of zero with the transmitter keyed in TUNE MODE.

Loss of 6146 screen voltage in TUNE mode, however, will NOT prevent the operator from achieving a peak ALC meter indication when adjusting the DRIVE control. The loss of 6146 screen voltage in TUNE mode prevents current flow in the PLATE circuit and a small amount of current flowing in the screen circuit ONLY. It has no affect on GRID current that results due to a positive segment of the driver stage's RF sine wave that causes the grids (pin 5) of the 6146 final tubes to become positive resulting in grid current flowing in the final tubes (cathode to grid)

Francesco,

You should make sure you have have checked and if necessary, perform the bias pot adjustment shown on page 21 in the TS-520 User manual first.

The TS-520 HV Unit board contains 2 resistor, R5 and R6, both are 56K ohms 1/2 watt each. In TUNE mode these 2 resistors on the HV Unit board form a DC voltage divider that reduces the final amplifier's screen voltage (pin 3 on either one of the 6146 tube sockets) by 50%.

The approximately 6146 screen voltage, pin 3 on the 6146 tube socket, in CW, USB, and LSB receive modes is approximately +258VDC. Place the MODE switch to TUNE (transmitter is NOT keyed) and the 6146 screen voltage should drop to approximately +146VDC.

Total resistance of R5 and R6 in series to ground is 112000 ohms

The current flowing in the series circuit with +258VDC applied to R6 to ground is 2ma

258 / 112000 = .002

The voltage drop across R6 is approximately 112VDC

Subtract 112 from 258 and the approximate DC voltage at the TUNE terminal of the HV Unit and pin 3 of the 6146 tube socket in receive is +146VDC

258 - 112 = 146

This "+258VDC" DC voltage may vary depending on the resistance values of R5 and R6 on the HV Unit board and the actual Rectifier Unit 210 DC voltage.

Today I had a litte spare time on hands and tackled the notch filter. I finally managed to find a deep notch following your method. Found out the hard way that trying to find a minimum volume on the speaker is hard with AGC switched on... I heard short dips when turning the core of L10, but couldn't find a real minimum.... the volume dipped shortly and went back up to the same level. Finally, it dawned me that the ALC will keep the marker signal on constant volume, switched ALC off and got the minimum easily. Ah yes, to get this old and still learning something new. The notch now has a depth of 3-4S steps, fine!

Thanks again for your help, Terry. I'm going to find out why the VOX isn't working next...

Hi Tim,
Many thanks for the info, I have checked all the voltages and they all seem fine.
Finals metering.
Pin 3: 256v on Rec and 114v on Tune. (256v on Tx as per manual).Pin 5: -100.1v on Rec, and -65.5v on Tune. (-62.5v on Tx as per manual).Pins: 1,4,6: 0v on Rec and 0.12v on Tune, (0.375 on Tx as per manual).
I suppose the next job is to check the send/receive relay unless anybody else has any ideas.
Thanks again
Brian

DEAR TIM

CONTROLLED BETTER THE TS-520 .
I HAVE READ THE FOLLOWING MEASURES :
TUNE IN POSITION, AND METER SWITCH IN POSITION:
IP - NO SIGNAL (ON METER TS-520) AND NO POWER
ALC - OK ALC LEVEL (ON METER TS-520) AND NO POWER
RF - NO SIGNAL (ON METER TS-520) AND NO POWER
HV - OK READ VOLT (ON METER TS-520)
IN POSITION CW AND CAR (ABOUT HALF) METR AND SWITCH IN POSITION
IP - OK READ CURRENT (ON METER TS-520) AND POWER OK
ALC - OK READ ALC (ON METER TS-520) OK READ AND POWER ON (ON METER TS-520)
RF - SIGNAL OK (ON METER TS-520)
HV - OK READ VOLT (ON METER TS-520)
WHY TUNE IN POSITION I HAVE NOT SOME ANSWERS (IP / RF)

THANKS FOR HELP

I would think the screen voltage to the finals could be missing in tune.

Check resistors R5 and R6 on the X43-1110-00 board.

Tim

Check the external speaker socket on the rear corner. I picked up one
with no
sound and it turned out there was no contact there. When plunged in with
an external
spk it cuts out the main unit. With no connector it returns to a full
contact. Clean the
contacts.

I have a video on my website that explains how the switched 3.5mm or
1/4" socket works. The EXT SPKR socket on the rear of the TS-530 is a
3.5mm switched socket, just like the larger 1/4" switched socket.

http://w5rkl.com/wp-content/uploads/2015/02/Quarter-inch-mono-switched-socket.wmv

The audio is almost always present on the socket's "tip" metal tab of
the 3.5mm or 1/4" switched sockets. Speaker is almost always on the
switch lever. Plugging the external speaker 3.5mm plug into the socket
separates the TIP from the Speaker lever on the socket, disabling the
speaker. Removing the 3.5mm plug from the socket and the TIP and Speaker
lever contacts is re-established, hence audio is heard in the speaker.

I don't think you should assume,

It's better to measure first and be sure. Check
the SP signal on the AF board with a 'scope, a
meter or a set of headphones. If you have audio
at that point then it's more likely to be a poor
connection on the front panel phone jack as has
already been suggested. If you don't have audio
at SP then start working backwards to Q6 and if
necessary trace AV2. There may be some other cause to your lack of audio.

It would be a shame if you went out and bought Q6
only to find the problem is elsewhere. No idea
where you'd buy one but I'm sure the stateside guys can help if you need one.

Regards

It's rather easy to determine whether R5 and R6 need to be change.
Simply follow the steps below, you only perform one measurement, the DC
voltage at the HV Unit's 210 terminal. The rest is simple basic high
school math.

Measure the DC voltage at the HV Unit's "210" terminal.

Next, use Ohms Law to calculate the approximate current flowing through
R5 and R6 series to ground circuit.

I = E / R

where "E" is the HV Unit's 210 terminal DC voltage you just measured and
"R" is the typical total series resistance of R5 and R6 which would be
approximately 112000 ohms. The answer is the current flowing in the R5
and R6 series circuit.

255 / 112000 = .002

Now use Ohms law to calculate the approximate DC voltage drop across R6

E = I x R

where "I" is the 2ma and "R" is R6's 56000 ohms resistance value.

.002 x 56000 = 112VDC

The answer indicates a voltage drop of approximately +112VDC across R6.

Now subtract 112 from 255 and you get the approximate DC voltage you
should see at the HV Unit's TUNE terminal and at pin 3 on both 6146 tube
socket.

If the DC voltage at the HV Unit's TUNE terminal is significantly lower
than the above calculations then you should replace both R5 and R6.

Mark,
One of them was me, with 2 guys in Texas also on the frequency much stronger and drowning out the net. I gave you a call about 3:15 central time but evidently you couldn't hear me. 73

Joe,

Thanks for the reply. That is one of the websites that I had found the net info on. So there was a net today and I just couldn't hear it? That's strange because I dialed around on 40m before I settled in to wait for the net and I was hearing pretty good signals from all over the country. Is the Kenwood net pretty localized? I'm in Idaho.

Mark, I was one of the stations trying to check in at the very end. You were 20 over so a good copy even with the broadcaster. Guess my 530 barefoot to a vertical is no match for mega watts. Thought briefly of signing in with CW but didn't know if that was acceptable practice.

As long as it's 15wpm or less. Been a long time since I've done any CW, sorry to say.

The broadcast station was about S9 here, which is very unusual. They are usually just down below S5, or so. With the time change, they will not be on at 3pm and go off at 4pm, so the first half hour we have to deal with them, but after 4 it's free sailing.

Mark, WB0IQK

>

Interesting behaviour: A signal generator with about 5 mVpp@1kHz at the microphone plug (pin 1 & 4) triggers the VOX (with VOX GAIN turned fully CW, i.e. maximum sensitivity). Using the original MC-50 microphone, it continued working (with VOX GAIN turned to about 12 o'clock). Both GAIN and DELAY are fully functional.

Using my usual microphone (a Shure 450MKII in "HI" pos) the VOX stopped working. I can shout as loud as I want, no reaction. On the other hand, the Shure 450 needs about 3 units less MIC for full ALC swing. With the MC50, I need to set the MIC to 6-7 for full modulation, the Shure 450 needs about MIC 3 for the same.

I'm completely stumped....

Martin

PS. 1/2 h later:

One should consult manufacturer documentation even when not provoked to do so. The PTT switch of the 450MK shorts the microphone capsule when not pushed... no wonder my cries for help didn't activate the VOX. 10s with a soldering iron made everything work perfectly now.

M.

53334. Hybrid Net Update (November 1, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-11-01 19:56:18 UTC
From: Mark Gilger
Topic: 53334 Message: 53334

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by me, WB0IQK. There
were 15 stations checking in under good band conditions.

We had the following number of radios checking in.

5 running TS-520(x)
2 running TS-530(x)
2 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-830s and Drake L4B amplifier.

The Sunday net was run by me, WB0IQK. There were
12 stations checking in under fair good
conditions. We had the following number of radios checking in.

3 running TS-520(x)
0 running TS-530(x)
3 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running a TS-520S with my L-4B AMP.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:

No, 1pm EST, which is 1800z since the time
change. The net is always held at 1800z.

We had 15 check-ins but had to move up to 14.319 due to QRM'er at 316.

Although i dont do digi modes with my TS-830S (i use my TS-440S for that) in order to do AFSK the manual recommends to use the Mic jack and either the speaker or headphone output. You need PTT, audio out and audio in to make the AFSK work for RTTY or other digi-modes.

The remote connector on the back has PTT and audio out bit no audio in. It is much easier to use the Mic and Headphone connectors.

Hope this helps you,

Topic: 53337 Message: 53340

Most sound card digital mode software, such as MixW, HRD/DM780, and others has both PTT and VOX methods of keying the transmitter. The operator simply has to select the desired method of keying the transmitter, PTT or VOX, in the software's configuration settings. Most sound card interfaces will work PTT or VOX, review the sound card interface manual for details on setting both methods of keying the transmitter.

Kevin also needs to specify the make and model sound card interface he has.

The TS-830 REMOTE socket 7 pin DIN socket has the following

Pin 1 - 100 to 150mv audio output
Pin 2 - Relay common, not grounded to radio's chassis
Pin 3 - PTT line (in parallel with the front panel SEND switch and the MIC socket PTT Pin 2 of the MIC socket
Pin 4 - N.O. (Normally Open) relay contact
Pin 5 - N.C. (Normally Closed) relay contact
Pin 6 - ALC "input" from external linear amplifier
Pin 7 - No Connection

The above pin identifications can be found in the TS-830 User's Manual, page 13 paragraph 15 "REMOTE CONNECTOR".

If PTT is used, the MIC socket pins 2 and 3 (pin 2 for PTT hot and pin 3 for PTT ground) are used.

Pin 3 on the rear panel REMOTE DIN socket does not have a PTT ground return and none of the REMOTE socket pins are connected to the chassis (ground return for PTT).

VOX is the easiest method of keying the transmitter when operating digital modes, RTTY, PSK31, AMTOR etc.

Regardless of the sound card interface, the TS-830 ALC meter, during digital mode transmissions, should never indicate ALC. Sound card interface TX audio levels are set by adjusting the sound card interface TX audio level pot inside the sound card interface, NOT the front panel MIC gain. The TS-830 MIC gain is adjusted for normal sideband transmissions and not re-adjusted when operating digital modes. Turn all audio processing OFF when operating digital modes!!

The typical power output when operating digital modes is between 20 and 30 watts max. PSK-31 is a low power digital mode. The TS-830 final amplifier and power supply are not designed to operate 100% duty cycle at high power levels and long "Geezer" type transmissions. Keep transmissions short.

Subject:[TS-520_820_530_830] Re: Bpsk31 and rtty

Although i dont do digi modes with my TS-830S (i use my TS-440S for that) in order to do AFSK the manual recommends to use the Mic jack and either the speaker or headphone output. You need PTT, audio out and audio in to make the AFSK work for RTTY or other digi-modes.

The remote connector on the back has PTT and audio out bit no audio in. It is much easier to use the Mic and Headphone connectors.

Hope this helps you,

73 de

Ron, I agree completely. So easy to just plug in to the mic and headphone socket when you need it. Ok, it's not as convenient as a permanent connection, but WTH.

Must get back into RTTY! I used to have a Creed 7B teleprinter. Now that was fun!

David G4TUP.

Hi Terry,
I am been away for some time. Many thanks for your input.Some answers : Q14 seldoms fails. Have you measured Pin 14 to ensure you have approx 5.6vdc? Yes 5.6V is there
Also would clean the contacts on RF board bandswitch deck S1-1. Easy to access with artist brush and few drops of Deoxit D5: did that but not sure to access key points.
I think you are saying that DCBA output from Counter Unit to the PLL board is stuck on 1000 in any of the bandswitch positions? I think you said you swapped out the PLL Board? or Did you mean you swapped out the Counter Unit board? I swapped out the PLL board and put another one : no result.
I assume you have measured the diode bias switching voltage (approx 8.9vdc) at the pins on Conn 3 as you switch the bandswitch? Dont just measure them at Conn 4. Yes I measured at Conn 3 . The band signal +9V is there.
You can also measure the input voltage to the 4 gate pairs. It should be approx 4.4vdc. Q14 : on 7MHz for instance, I have 9V on Conn3#7, on Q14 12-13 are at 4.4V, 11 is at 1.3, all others are at 0V except 4 at 4.4V and 3 at 1.3V.
I have to measure the levels on the PLL board : I checked with the spectrum analyzer that the signals CAR, VCO, VFO are there, but have to check voltages.
You are right I should have a working rig on 1.5 and 29.5 with DCBA=1000. As it's not the case something else is missing.

  I forgot to mention if you have 1000 DCBA input to the PLL board did you check to see if you have approx 1v rms VCO signal level output from the PLL Board on 1.5 and 29.5 bandswitch positions?
I would measure the VCO level at TP-3 on the RF board. If no VCO on either of those two bands make sure you have approx 200mv rms VFO input signal level at PLL board Conn 6. I believe you said you verified that you had 300mv of CAR oscillator? Also, make sure you have 1 mhz clock at TP-2 on PLL board.
Even if the Counter Unit only has DCBA output of 1000, Should have operational rig on 1.5 and 29.5 bands.

I have had the same experience. But I think the culprit is the switch on the PLL module that selects between Tune and Operate. You see, that is a simple slide switch and it controls where the voltage that controls the VCOs (one for each band that share a common control voltages source). In the operate it routes the voltage off the phase comparitors to the VCOs. In the Tune position it provides a fixed voltage that lts you tune the center frequency of each band"s VCO. If it open circuits, then the VCO get no or some odd control voltage and the PLL won't lock. Clean that switch and see if your problem goes away. I chased this for a while and while I did find some other issues I think they were all related to not getting the right voltage on the VCO control lines,

The TS-530S does NOT have a "tune/operate switch" on the PLL board,that is on the TS-820(S) model. I would suspect, from what the poster stated, that there is some corrosion on one or more "molex" connectors. They should be cleaned with your choice of cleaner/lube....which one...up to you..as that's been a topic of numerous "discussions." CAIG DeOxit is a good and popular one...there are others

Addendum,
  RL-1 and/or the TR relay may have corrosion on the points. It not uncommon for RL-1 (on the IF board) to malfunction after numerous cycles and also sitting unused. Cleaning the points of RL-1 may only solve the problem for a very short period of time. The relay is small..and the points are delicate and do not take kindly to cleaning by manual means.K4eaa"dot"com has a very good replacement if your RL-1 proves to be defective. It will most likely outlast you AND the rig

It has an AM position on the mode switch; has a 6 KHz filter, has the AM board. Wiring to integrate this stuff means some wiring differences between 830M and 830S. Service manual covers 830S and 830M. AM power output should be kept to 25 watts or less. Especially less if you're long-winded and key-down for many minutes.

Danyy,

If you do not have the TS-830M User's manual, I have it on my website,
click on the following to download the manual.

http://w5rkl.com/wp-content/uploads/2014/04/TS830M-operators-manual.pdf

There are differences in how to adjust controls to achieve certain meter
indications to operate AM mode that you will not find in the TS-830S
user's manual.

For example, the CAR control, in sideband, is disabled but the CAR
control is not disabled in AM mode. The "CAR" control is used in AM mode
to set the maximum 130ma IP current.

Also, when operating AM, the MIC gain is adjusted so the ALC meter
indication "slightly moves on voice peaks". This is not the same ALC
meter indication you would adjust the MIC gain for when operating
sideband (USB or LSB).

I recommend you download and spend time reading the TS-830M users manual
before you operate you TS-830M.

Purchased a clean TS-830S with a MC-50 microphone recently. It had been in storage for about eight years and was DOA. After cycling and cleaning all switches, the receiver came alive, almost, but still no TX. Found that L16 (IF) would not peak. Replaced with one from a donor TS-440. TX and RX came alive, but low TX. Then found that L28 (IF) bad, would not peak. Replaced with part from the donor radio. Got it playing, but still low TX on upper bands. Then it quit - no TX. The 12BY7 tube socket had at all pins fractured or missing solder joints. Works much better now. Full re-alignment may fix the low TX issue to come shortly. B+ is 800vdc no load and drops to 700vdc under load. What is normal for HV? I will replace HV filter caps soon. Your comments on these issues are welcome.

I am new to this forum and this is sorta my introduction. Have restored some old Hallicrafters receivers and thought I would move up to transceivers. My plans are to have a Vintage station consisting of the TS-830S with my existing SP-230 and SM-220 less BS-8. Any one got a spare BS-8? I have a VFO-230 on the way.

Tom,
Congrats on your new rig.
I suggest that you stop what ever you are doing on the rig until you get the HV caps replaced! They are showing signs of failure...low resting voltage...low voltage under load. I assume that you are checking the voltage using the front panel meter? Even so, a catastrophic failure of one or both will ruin your day..if not the rig. Resting voltage should be around 850VDC...voltage under full output (100W nominal) should be within 10-12% lower...say an average of about 750VDC. These voltages are not exact..they can vary slightly...but you'll get the idea

There are several kits available, or make up your own.
  Look at: hybridrestore"dot"com
               k4eaa"dot"com

Hi Joe:

I am using a VTVM to measure the HV. For this measurement I didn't trust the panel meter, although it is close to the VTVM. Thanks for the heads up on the caps. And yep, I have the caps on the way from Hybridrestore. I'll let radio rest until replaced.

Thanks, Tom, N5AS

Jean:

I would measure the VCO levels at minimum on 1.750mhz and 28.750mhz (vfo at 250) on the RF board at TP-3. Does no good to measure on the PLL board and call it good. Always need to confirm you have good VCO signal at TP-3. You need approx 1.0rms rf volts at TP-3 on the RF board as the VCO is the LO for the RIF Mixer and TX Mixer.

If you have no VCO signal or very low level at TP-3 you wont have any receive or transmit, but will have digital display.

If you have no VCO signal at TP-3 then go back to PLL board and measure at the Cathode of D40. If you have good level at D40 then look at coax from PLL to RF board.

The small black coax cable that routes the VCO signal from the PLL board to the RF board can be problematic. Can have a bad solder connection on the center pin of the male plug on either end of the coax and/or can have bad solder connections on the PC board mounted sockets both center conductor and shield.

If your display is Blank then you wont have any VCO signal from the PLL to RF board as the Blanking voltage (approx 4.6vdc) is sent to switch Q22/Q9 which will shunt the VCO output from Q8 to ground.

If Display is blank and no VCO signal then for starters you need to make sure you have proper VFO and Carrier signals at Pins 2 and 5 of 1st Mixer Q40. Should be approx 120 mv input on Pins 2 and 5 and approx 120mv output on Pin 1 (14.3 to 14.8mhz).

Thanks for the response

I have the user manual so will have a read. The radio is essentially NOS – absolutely mint. Think the original owner bought it, left it in the box for a rainy day and never used it.

The box is mint, the manual is mint and it even has the little ‘goody bag’ with the various plugs etc still stapled shut. Really is as perfect as they come.

I hardly dare use it!

Danyy,

If you do not have the TS-830M User's manual, I have it on my website, click on the following to download the manual.

http://w5rkl.com/wp-content/uploads/2014/04/TS830M-operators-manual.pdf

There are differences in how to adjust controls to achieve certain meter indications to operate AM mode that you will not find in the TS-830S user's manual.

For example, the CAR control, in sideband, is disabled but the CAR control is not disabled in AM mode. The "CAR" control is used in AM mode to set the maximum 130ma IP current.

Also, when operating AM, the MIC gain is adjusted so the ALC meter indication "slightly moves on voice peaks". This is not the same ALC meter indication you would adjust the MIC gain for when operating sideband (USB or LSB).

I recommend you download and spend time reading the TS-830M users manual before you operate you TS-830M.

Hi friends,

I'm kind of sad here.
I sent my 830S for maintenance and alignment ...
He returned almost the same, bought two valves 6146B of PENTA (made in china) they did not present good pwr and BIAS only came at the right point to the pot. all rotated.
The person who made the maintenance said they would not do!
In 10m does not provide more than 30w, it has a coil of red nucleus broken and allows adjustment ...

Some things that were requested were not checked.

Inclisive the smeter, this does not measuring right, and then I ask:

I discouraged tried to adjust the force! I changed the VR2 and VR3 together with L9;

in L9 with disconnected antenna sought the greatest white noise;
reguelei the VR2 to S1 in smeter;
the VR3 with connected antenna and a reference signal S9 tried, but it did not ...

So in 40m but smeter unsigned gets S1,5 and failing station signal having the radio next to S5, the 830apresenta S2 or 3 ....
in the bands above 40m, the smeter hardly deflects ...

The RX this good, compared to my INDEX.

In TX 21400'm in, 220mA / 800V, swr 1.0 ....

Well my dear friends if someone can give me an orientation I appreciate as it gave a very great dismay,

Excuse me some mistake in writing because I am using the google translator and I had no patience to review the text ...

From: wagstw46@...
Topic: 53362 Message: 53363

There is no bearing. It is bushed with the OD of the bushing fit provided by push fit in a hole in thin front metal plate.

Some people disassemble the VFO and remove the front plate and use a sharp punch and prick punch a series of close spaced holes around the circumference of the hole to raise the metal to reduce the ID of the hole and then press the bushing back into the plate. This is a lot of work and not sure it will be very long lived fix? Might be able to secure it with some epoxy like JB Weld if the metal is cleaned of all traces of lubricants.

It is normal to have a small amount of axial play but the radial play that you describe is the result of wear and not normal. It is indicative of rig with many hours operation on it. Is this a 1 Million series radio?

Gordon Benjamin N6WK use to install a small thin cupped belleville spring metal washer on the shaft and behind the c-clip retainer to eliminate the axial play. He bought these from auto rear brake repair kits. These washers are used on the emergency brake mechanism. I think you can search on Conversations and find his post on this topic.

This is another reason to own a VFO-240 remote VFO. Most have far fewer lock to lock revolutions on them and you can equalize or share the wear. Other option is of course to buy a used pulled VFO off Ebay, but no idea if it will have any less radial play. Sometimes you get lucky.

I am investigating the broken wires on the WWV switch on my 520.

There are 4 broken wires all of them are grey shielded wires.One side of the switch has a violet, Orange and red/white striped wire. Those are all attached well. The gray, shielded ones all fell off when I breathed on them and I have traced them thus:

goes to JAT/GND on RF board goes to 12 pin Xverter Plug Goes to MO/GND on Marker Board Goes to Relay RL-2 (one under the metal cover on the underside of the rig)

Here is what I can figure from the schematic

back of switch Terminal side Front of rig

JAT MO ?
# # #

# # #
Red/Wht Org Violet

I can't tell were the ones going to the relay and the Xverter Plug go.

The rig does not RCV with the switch on or off. when the WWV switch is in on the Meter rises to full scale.

Nothing make the rig make any noise i.e. tapping on relays. cycling band switches
The function switch is the only thing that does,
There is adjustable bias on TX but no other signs of TX
New driver and and new finals

HELP!

From: hackmohr@...
Topic: 53367 Message: 53367

Hello All,

First time here. Hoping I can get some pointers on re-lubing my TS-520 VFO. It has what I would describe as a "lumpy" tuning feel to it. At various places along the rotation you can feel a bump. If you try and tune in where there's a bump the dial slips up or down a few hundred Hertz. There is no problem with warbling or the VFO dropping out. It feels like a mechanical not electronic problem. I'm preparing to pull the VFO and clean out the front end of the shaft with the ball bearings. I'm assuming the 30 year old grease in there has hardened and needs to be cleaned out and replaced. Any hints or tips on disassembly and re-lubrication would be appreciated. Thanks.

53369. Using a SDRplay as panorama adapter with the TS830S

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-11-06 18:26:00 UTC
From: Martin Jangowski
Topic: 53369 Message: 53369

Got a new toy a few days ago: a SDRplay receiver. This one is capable of receiving from 100kHz to 2GB and proves to be an excellent RX when used at my ham antennas (RF and UHF).

I bought this thing to use it as a panorama RX at IF1 of the TS830. This works like a charm, a screenshot (quite large) can be seen at

http://www.jangowski.de/SDRplay_as_panadapter.png

The screenshot shows the first IF of the TS830S tuned to 7.176 kHz LSB. You can see the wide traces of two broadcast stations at >7.200 kHz. The right halve shows the 40m ham band with several QSOs taking place. The TS830S is running at LSB, the station you can hear is at 8828.5 kHz at the SDRplay.

One thing is interesting (and unexpected for me): everything is reversed. To listen to the QSO via the TS830 IF, I have to switch the SDRplay to USB. The ham band ranges from 7.000 to 7.200, it is visible a the higher end (right side) of the screen. This makes is a great tool to watch the band and listen in for interesting QSOs, but not too easy to tune the TS830 afterwards... you have to subtract the IF frequeny of the TS from the frequency showed and tune the TS the same amount downward, if the result is positive (and upward, if not). This isn't very easy or fast, but this cheap SDR radio (about $150 in the states) has an excellent value for the money and is useable right out of the box as a modern panadapter for the TS830S...

To follow up my own posting: this is to be expected if the oscillator
frequency is above the received frequency. A smaller difference between
received frequency (= higher rec. frequency) and oscillator frequency
(constant) yields a smaller IF frequency. So everything is mirrored at
the IF, USB becomes LSB etc.

Hi Martin,

Yes the sidebands are inverted at IF1 on the
TS830. I see you are using HDSDR software. I
don't know this software but it seems there are
some settings (RF Front-End + Calibration) that
allows spectrum inversion for the display. This
may make operation a little less confusing.

I think there was some discussion about SDR some
time ago (maybe 12 - 18 months) and perhaps a
presentation from Dayton regarding how to use SDR
with Kenwoods. Someone else may remember where to find the presentation.

For reversed sidebands check Options [F7]

then look at "Swap I and Q Channel for RX "

Great, can't wait to try it (tomorrow, it's close to midnight here in DL).

Thanks for the info,

JB Weld. I cannot tell you how many times JB Weld has come to the rescue in repairing radio equipment, antique and new. I have found the 5 minute JB Weld to be useless, only use the original 24 hr. dry. It can be sanded, filed, painted and drilled. Rich K8UV

53376. TS-820s Questions

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-11-07 17:41:10 UTC
From: tsnarcher@...
Topic: 53376 Message: 53376

Hello All, Recently I purchased a TS-820s from the family of a SK, very very clean, included the owners manual, Service manual, and even the original box.
After getting the rig on the table and familiarizing myself with it I began tuning using K4Eaa's tuning procedure which is the same procedure I use for my TS-530s.

After following the procedure this is where I am at:

Tuning the 20m band into a 50 ohm dummy load

Carrier position-approx 1.5 (about 8 o'clock).
Load-1 o'clock
Drive- 12-1 o'clock
Plate-Middle of the 20m arc

With an IP reading of 220ma, according to my watt meter I have output of around 35-40 watts.

Now for the "kicker" stapled in the owners manual is a typewritten letter detailing modifications performed by the original owner, the letter is 5 pages long, but the pertinent (at this point) is as follows:

"The modification increases the output power from approximately 95 watts to 135 watts by raising the screen voltage from 210 volts to 300 volts".

It goes on to describe some wire cutting swapping voodoo concerning C22 C23 and C24, replacing resistors.

My ultimate goal is to return the radio to its original state, but this morning my question is this: is the low output due to components being damaged by the QRO mod, or for the time being do I need to adjust my IP reading during tune up to 300 volts + or - to achieve normal output?

I am not a fan of these mods, and would be happy with the normal 95-100 watts out. Sorry for the length.

Tom,

I ran into this kind of mod in a TS-530S. Basically, the mod involves disconnecting the 210A supply and hooking it instead to the 300V supply to increase the screen voltage on the finals. The prior owner actually clipped the 470 ohm resistor in the 210A screen circuit to disable that supply. The mod may include substitution of resistors in the bias adjustment circuit as well.

Your final tubes (6146B) may be cooked and the final amplifier cathode (R2 & R3, 10 ohm) and/or screen (R5 & R6, 100 ohm) resistors may be bad. These should be checked immediately. The cathode resistors in my radio were cooked (reading high), and this affects output. Look carefully at the plate choke in the final amplifier for discoloration (it's the tall one between the two 6146B final tubes). This can be stressed by HO operation and appear blackened or darkened (maybe indicating some shorted windings).

Check the divider resistors in the TUNE circuit; R5 & R6 (56K) on the HV board. I'm not sure which caps the letter refers to, but the HV caps are designated C21 & C22, and the screen supply caps are designated C23 and C24. These may have been fiddled with as well. C23 and 24 are dual caps.

Sometimes this "QRO" mod is done by CB operators for high-power 11 meter operation. You should scan the "letter" and the radio to see if crystals, band switches and other related components have been fiddled with. This was the case in my radio. These kinds of mods can affect operation/power on other bands.

My advice is just to un-do whatever has been done. You at least have a detailed description of what was done-sometimes you just have to figure it out.

The QRO mod is a particular puzzle-the difference between 100W and 135W is not really discernable on the receiving end.

Good luck with the radio!

Dave KC3CIP

53380. SM-220 woes

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-11-08 07:40:38 UTC
From: Martin Jangowski
Topic: 53380 Message: 53380

Got a brand new looking SM220 from the estate of a SK ham. Positive:
Nice looking on the outside, sharp straight trace. Negative points: the
plastic coupler at the input switch is broken (are these are the same as
the ones used in the TS-series?), and the only thing moving the trace
vertically is the position pot.

Can't be too serious, going to inject signals into the vertical amp
until the trace is moving....

Any additional hints for the bug hunt?

Martin DB2MJ

From: Mike W5RKL
Topic: 53385 Message: 53385

No David, this is NOT a scam.

YES David, every member is required to add an acceptable message signature to the end of every message the member posts on this group, whether the member is a licensed Amateur Radio operator or not.

The Yahoo Kenwood TS_520-820-530-830 Group policies can be found at the following links:

1.
https://xa.yimg.com/df/TS-520_820_530_830/Message+on+approved+membership.txt?token=C8W3zSPtiOrux_utnUoxnCZsFzMDwAOZ6Gv55ltRkPifUspgWO_Ak9tsERgbwwg4fAf0JesF_LYHQgrqGWuWzfoeVPXl_I1k0vPSFAv62y70ONWFHaJyfUauG7gzI_3BleIXL6Fc2RzMFRlVVPjUS2JhFVUHoUo&type=download

or

2.
http://w5rkl.com/wp-content/uploads/2015/02/Message-on-approved-membership.pdf

There are only 2 acceptable message signatures which examples are shown in the group policy message and they are as follows:

1. Members first name only (family name is acceptable in place of first name)

or

2. Members first name followed by their Amateur Radio call sign

Use of "73" as part of the signature is optional.

The member, whether a licensed Amateur Radio operator or not, has the choice of either signature "1" or signature "2". The member decides which one they will use.

Unacceptable or assumed to be acceptable message signatures are:

1. The member's "initials"

2. The member assumes his/her email address in the heading of the message is sufficient enough to qualify as a message signature.

3. A screen name the member uses elsewhere and/or is part of his/her email address

4. The members email address added to the end of the message

73

I finally made it in to the net for the first time today. The noise on my end was really low, probably S2 or so but net control was pretty weak too, about S3-4. There was some REALLY BAD intermittent QRM on my end that was coming in at S5 and completely covering the signals but I was finally able to hear the call for late check-ins and slipped my callsign in there. Maybe when the band is in better shape I'll actually have more to say.

Also, on a side note, is there any way to set up a signature block that automatically puts my signature at the end of my messages. I forgot for the second time today and I fear that if it happens again, the signature nazis will boot me from the group.

Chris-af7fq,
  Look at the upper right of your screen for a symbol that looks like a "cog wheel." Hover cursor over it, click on "settings," click on "accounts," to the right your should see a couple of boxes under the heading "Email Addresses," click on the "Yahoo" one. enter your information in the boxes, and "save." Now, every msg you post here will be appended with the "signature" you entered. REMEMBER at a minimum: first/given/Christian name are REQUIRED for all posts/msgs.

From: Joseph Stiles
Topic: 53389 Message: 53389

Greetings group,
Again, there seems to be some confusion regarding msg/post signing.
   All members when initially accepted to the group, were automatically sent an electronic copy of the group policies. It seems many do not take the time to read it, and therefore run afoul of the group's administration. Every once in awhile, a moderated message will make it through the review process without the proper signature. The moderators and I try and keep the BS to a minimum. Two moderators are in the mid-west area, and usually handle the early traffic. I'm on the west coast and usually deal with the later stuff. We ARE NOT here 24/7/365, and at times, believe it or not... have other things to take care of, especially on holidays and/or summertime. So, for group members that are on "moderation," don't freak out if your post takes maybe 24 hours to get reviewed, and either approved or rejected.
 It was asked: why do we have to sign msgs/posts?
     don't groan...but simply..that is the rule/policy, and has been in place since before I came to the group. Email headers/address, or screen names, my not indicate whom is posting...say "barfbucket@pigswill.biz....so therefore the requirement to sign at the end of your post with at a MINIMUM your first/given/Christian name. If your are a licensed amateur radio operator, it would be nice to include your call also...but it's not required, as some members don't have a ticket, or are working on it. I don't suppose that you would send a letter, or other correspondence, without properly identifying who it came from...same here. It's just nice to know to whom we are "talking to."

Mike-w5rkl, has kindly posted links to the group policy in his recent email. Thanks, Mike.

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by Jimmy, WB2KNR.
There were 23 stations checking in under good
band conditions. There were 5 new check-ins,
K8HJU, KM3F, KA1FGL, KA1LDL, and KI4DKX.

We had the following number of radios checking in.

4 running TS-520(x)
3 running TS-530(x)
1 running TS-820(x)
7 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

Jimmy ran the net with his favorite TS-520.

The Sunday net was run by Jimmy, WB2KNR. There
were 19 stations checking in under poor
conditions. There were 6 new check-ins, K4DTR,
W4IBG, AF7FQ, KG0PP, WA0PMO, and KJ4AUQ.

We had the following number of radios checking in.

6 running TS-520(x)
2 running TS-530(x)
1 running TS-820(x)
4 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

Jimmy ran the net with his favorite TS-520.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 □ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins
Nov. 2014 □ Oct. 2015 Saturdays total 962 check-ins, Sunday total 669 check-ins

November 2015, Saturday□s net total = 23,
Sunday□s total = 19 (Month to date)

53393. Worn out SO239

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-11-09 01:51:49 UTC
From: Rob
Topic: 53393 Message: 53393

All,

I have a 300 series TS830s with a worn out SO239. Problem seems to be that the center conductor no longer makes good contact. I run RG-213 from the radio up to the balun of a wire dipole.

I've been using the rig almost daily and I disconnect the antenna every time I'm finished. (I also leave the cable outside the house, not wanting to risk having a strike follow my cable into the house.)

Anyway, I have probably been the one to wear it out. I do not have a static drain or spark gap system installed yet. But I'm not sure I would trust any lightning protection system to fully protect the rigs from a strike.

So my question is, what does everyone else do? Is there another way to quickly disconnect the antenna without wearing out the connector on the rig? Or is there a protection scheme that is effective enough that I wouldn't need to worry about a direct antenna strike?

Thanks,
John

Hi Rob,

Since you already disconnect the cable and
leaving it outside why not look at something like
the MFJ 4602 antenna panel. Probably solves a lot
of your issues right there.Lightning protection
is serious business and commercial installations
spend A LOT of money getting that right. Most ham
quality lightning protectors will probably only
help to discharge static build-up. It's unlikely
they will protect from a direct strike.

John,

Apart from having a great earthing system, you have several options. I personally use a patch panel and N type connectors, this connects to its own earth which is completely tied into the main house earth system, 10x 3m 25mm earth stakes at 1.5m intervals. This inturn connects to the house earth and my 25mm copper water pipes. It is good practice to disconnect when not in use. I do not rely on earth positions on antenna switches or

73s
Dave
VK5PDL

lightening discharge inline connectors. I do have them installed at the patch panel for all the high mounted antennas. I go a little overboard and when the coax is removed, I then have a series of connectors that screw onto the patch panel and goes to earth.

Really as long as the 3 or 4 leaves are still good in the connector, all you need to do is bend them inwards. I have never gone to the extreme of unplugging my antennas from the radio and throwing the cable outside. Nothing can protect you from a direct strike and polyphasers are the best protection and are as good as the ground you provide. My antennas and radios are protected by a ground rod 6' in the ground and tied to my electric ground in one continuous run. The other thing you can buy is a shorting type antenna switch. Again only as good as the ground you provide. This way all you need to do is turn the switch and it will ground it for you. The idea behind lightning is the path of least resistance. What you need to do is PROVIDE a path for the lightning to go, then it will not go elsewhere. You can't prevent a direct or indirect hit, but you can with the right know how control where it goes. I really have never seen a bad SO239, but I have seen them where it does not seem to touch the center pin. Just bend them in and I would also check the soldering of the connector inside the radio.. You can also get a push on collar for the so239 eliminating the possibility of cross threading the connector. Do spend the extra dollars to get a decent new connector, not the radio shack quality out there. Maybe like silver dipped. Instrument quality connectors are best. Purchase the insurance from the ARRL which will provide you with the cash to replace your radio and equipment. Very reasonable and good to have.

Hi John,

The biggest problem with any kind of lightning protection system is you have to dissipate the huge currents and potentials in a damn good earthing system. Professional installations often use large copper backplanes connected to an efficient earthing grid. This is not something you can easily and cheaply do at home, so my advice to you is to stick to the good old "disconnect the antenna when storms approach" philosophy.

Why not make up a small coax patch cord with a SO239 inline socket on one end and a PL259 on the other. That way, every time you unplug the antenna cable you will just be wearing out the connector on the patch cord that you can easily replace.

Personally, I disconnect my antenna from my antenna tuner. This also has an easily replaceable SO239.

By the way, you can probably repair your connector on the 830 using a fine screwdriver to bend the central brass part of the socket back together.

Cheers,
Peter - VK2AN

Oggetto: Re: [TS-520_820_530_830] Re: TS-520 NO SIGNAL CURRENT IP IN TUNE MODE

  It's rather easy to determine whether R5 and R6 need to be change. Simply follow the steps below, you only perform one measurement, the DC voltage at the HV Unit's 210 terminal. The rest is simple basic high school math.

Measure the DC voltage at the HV Unit's "210" terminal.

Next, use Ohms Law to calculate the approximate current flowing through R5 and R6 series to ground circuit.

I = E / R

where "E" is the HV Unit's 210 terminal DC voltage you just measured and "R" is the typical total series resistance of R5 and R6 which would be approximately 112000 ohms. The answer is the current flowing in the R5 and R6 series circuit.

255 / 112000 = .002

Now use Ohms law to calculate the approximate DC voltage drop across R6

E = I x R

where "I" is the 2ma and "R" is R6's 56000 ohms resistance value.

.002 x 56000 = 112VDC

The answer indicates a voltage drop of approximately +112VDC across R6.

Now subtract 112 from 255 and you get the approximate DC voltage you should see at the HV Unit's TUNE terminal and at pin 3 on both 6146 tube socket.

If the DC voltage at the HV Unit's TUNE terminal is significantly lower than the above calculations then you should replace both R5 and R6.

Hi Terry,
As frequency display is blank and only hum no signal on rx, I checked Q40 on PLL board as you suggested. Signals are as you tell except that amplitude is 200mV pp. VCO is producing signal according to band switch (1.5V pp) but the signal is blocked after Q7 (PLL unlocked). I have 3V pp of 1MHz on TP2.DCBA output from counter unit and input to Q16 is still stucked to 1000 whatever the band.
What could I try next?
Thanks for your help,
73 de Jean-Louis F5DYD

  Jean:
I would measure the VCO levels at minimum on 1.750mhz and 28.750mhz (vfo at 250) on the RF board at TP-3. Does no good to measure on the PLL board and call it good. Always need to confirm you have good VCO signal at TP-3. You need approx 1.0rms rf volts at TP-3 on the RF board as the VCO is the LO for the RIF Mixer and TX Mixer.
If you have no VCO signal or very low level at TP-3 you wont have any receive or transmit, but will have digital display.
If you have no VCO signal at TP-3 then go back to PLL board and measure at the Cathode of D40. If you have good level at D40 then look at coax from PLL to RF board.
The small black coax cable that routes the VCO signal from the PLL board to the RF board can be problematic. Can have a bad solder connection on the center pin of the male plug on either end of the coax and/or can have bad solder connections on the PC board mounted sockets both center conductor and shield.
If your display is Blank then you wont have any VCO signal from the PLL to RF board as the Blanking voltage (approx 4.6vdc) is sent to switch Q22/Q9 which will shunt the VCO output from Q8 to ground.
If Display is blank and no VCO signal then for starters you need to make sure you have proper VFO and Carrier signals at Pins 2 and 5 of 1st Mixer Q40. Should be approx 120 mv input on Pins 2 and 5 and approx 120mv output on Pin 1 (14.3 to 14.8mhz).

Just picked up a TS830s

Receive sounds fine.

When setting up to transmit, there is no grid bias.

Any thoughts?

Jim,

I assume you mean, when adjusting the rear panel BIAS pot for 60ma indicated on the IP meter, the IP meter is resting at zero when the transmitter is keyed in USB or LSB. If so then check the rear panel "SG" switch, it should be set to "ON"

Jean Louis,

Sorry I have not kept up with this thread. I must assume seeing Terry, has been helping you that you have checked the 12volt and -6volt supply voltage to the board.

Don't just check at the molex connectors measure on the board as well.
Terry, helped me with a similar issue some years back when I was getting back into servicing. I had voltage at connectors but not further into board. I used external power supply 12 v and -6 volts. Found hair line cracks.

I have seen 5x 530s that have no display due to cracks on the counter board.
Apologies to Terry, for butting in and not keeping up

Jean:

I agree with Dave that you should focus efforts on the Counter Unit and not the PLL board. You could continue down the mixing scheme on the PLL by moving next to the Emitter of Q35 and on toward input to Q15 etc, but I dont think the PLL board is the issue especially if you tried another board with no change?

Also, given that DCBA does not change with bandswitch positions that isnt a PLL board problem.

I am pretty sure I previously mentioned measuring the dc input (12vdc) and the signal inputs (1K and Con) to the Counter unit?

I would also do the following:
1. Unplug and clean connectors 4 and 5 (diode matrix input) on the Counter board.
2. Unplug and clean connector 1 on the RF board
3. Clean bandswitch contacts on deck S1-1 on the RF board
4. Measure Pin 14 of Q14 and/or Q9 to prove that Zener D1 supply is working (approx 5.6vdc)

Jim,

None of the KW hybrid meter switch positions display "grid bias".

The meter, when the meter switch is set to IP and the bias pot is adjusted for 60ma indication in either USB or LSB, is not displaying "grid bias". The meter is actually displaying 6146 "cathode current" which is not "grid bias" voltage.

If, for example, your TS-830 loss final tube "grid bias" voltage due to a failure in the Rectifier Unit's "-C" supply, both 6146 final tubes would conduct to saturation levels whether the transmitter is keyed or not. This could easily cause the fuse to blow due to the excessive high current flowing in both 6146 final tubes.

I suspect what you are seeing, loss of "IP" meter indication with the transmitter keyed in USB or LSB modes, is quite possible as I stated in my initial response, due to the SG switch being set to the wrong "OFF" position. The SG switch OFF Position is not used for normal operation (see the TS-830S operator/user manual for details on using the rear panel "SG" switch).

Thanks to all who contributed suggestions for coax cable disconnection and station grounding schemes. (probably should have posted to the antenna group) John WA3JRS

On Monday, November 9, 2015 11:54 AM, "pe130700@... [TS-520_820_530_830]" <TS-520_820_530_830@yahoogroups.com> wrote:

Hi John,

The biggest problem with any kind of lightning protection system is you have to dissipate the huge currents and potentials in a damn good earthing system. Professional installations often use large copper backplanes connected to an efficient earthing grid. This is not something you can easily and cheaply do at home, so my advice to you is to stick to the good old "disconnect the antenna when storms approach" philosophy.

Why not make up a small coax patch cord with a SO239 inline socket on one end and a PL259 on the other. That way, every time you unplug the antenna cable you will just be wearing out the connector on the patch cord that you can easily replace.

Personally, I disconnect my antenna from my antenna tuner. This also has an easily replaceable SO239.

By the way, you can probably repair your connector on the 830 using a fine screwdriver to bend the central brass part of the socket back together.

Cheers,
Peter - VK2AN

Rory:

No disrespect but the DG-1 has nothing to do with the RF board or the Power Amplifier (PA).

DG-1 gets Carrier input from the IF board and VCO input from the PLL. It gets bandswitch info from the PLL. The unit is sensitive to signal levels especially on 10 meters. However the biggest issue is the well known poor soldering especially with the vias or plated thru holes. You can do key word search and find numerous posts on this forum about reflowing solder connections and cleaning of molex connectors both board and intra-board connectors.

Jim,

Since the SG switch is set to ON check the following:

1. Power up the TS-830 and check to ensure both 6146 filaments are lit. Requires the top and bottom cover and the cover over the final amplifier to be removed.

2. Check the 6146 cathode resistors (there are four 20 ohm 1/2 watt cathode resistors wired in parallel).

Use extreme caution when performing #1 as there is high voltage present on the final tube plates at all times when power is applied to and the TS-830 is turned ON.

Use caution by removing the TS-830's 120VAC wall outlet plug and allow the power supplies to bleed down to zero. Check the HV using a DC volt meter measuring the DC voltage at the plate caps of the 6146s. You can verify #2 by measuring the final amplifier cathode resistance between the 6146 tube socket's pin 1 and the chassis.

Mike,

Since I'm having a similar issue, I checked both points you mentioned. I see orange glowing coming from the tubes, and I checked the resistance between pin 1 and the chassis by using the solder connection on the underside of the board the tubes are on. If my math and meter are correct, this should read 5 ohms, correct?

Thanks,

Robb

Robb,

Yes you're right, the approximate normal final amp cathode resistance is 5 ohms.

I don't know what formula you used but a simple one, assuming all the resistors in parallel are the same value, four 20 ohms resistors in this case:

20 / 4 = 5

You can calculate the approximate final amp cathode voltage, power dissipated in the cathode circuit, and other values using simple Ohms Law formulas.

For example, assuming the IP meter indicates 350ma and the cathode resistance is 5 ohms, then the cathode voltage would be approximately +1.75VDC. This would result in an approximate power dissipation in watts in the cathode circuit of slightly over 1/2 watt, approximately .6125 watts (612.5mw). The total power rating of the final amp cathode circuit is 2 watts with 5 ohms of cathode resistance. Divide .6125 watts by 4 and each cathode resistor would dissipate approximately .153 watts (153mw).

It's fun to play around with different values to see what difference, if any, those changes would make.

Mike & Deb,
Welcome to the group and getting your "tickets!" I think you'll enjoy your new station. Read up on the proper tune up procedure in the Instruction Manual to get familiar with the location and function of each control and make some "dry runs." Also, PLEASE us a dummy load when tuning up your rig. Many are available, or you can build your own, just make sure that it can handle 100 watts.
Also, you can go to the group home page and look through a rather extensive files section. Several group members also have extensiveinformation files you may be interested in: Gordon(sk) n6wk"dot"com Mike-w5rkl w5rkl"dot"com Ron-wb4hfn wb4hfn"dot"com Jim-ke7oay hybridrestore"dot"com Ken-k4eaa k4eaa"dot"com
Again, WELCOME to the group

Due to QRM, the net moved up to 14.318. I have a similar problem on the saturday net in that 7.235 is used here in the southeast as a local ragchew frequency from Texas to Alabama....so I hear the locals who don't care a net is being held, they think they own the frequency. The Sunday issue is usually intentional interference by KZ8O because he hates nets. 73

53426. Hybrid Net Update (November 15, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-11-15 23:42:31 UTC
From: Mark Gilger
Topic: 53426 Message: 53426

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by me, WB0IQK. There
were 23 stations checking in under good band
conditions. We had a new station, W3CWE that
checked in using his TS-520D model. I think this
is the 2nd one of these we have had check in
since the net started 4 years ago.

We had the following number of radios checking in.

4 running TS-520(x)
3 running TS-530(x)
3 running TS-820(x)
4 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-830S + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
19 stations checking in under poor conditions.

We had the following number of radios checking in.

2 running TS-520(x)
4 running TS-530(x)
2 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
1 running 599 twins
0 running TS-900

I was running my TS-520s + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 □ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins
Nov. 2014 □ Oct 2015 Saturdays total 962 check-ins, Sunday total 669 check-ins

November 2015, Saturday□s net total = 40,
Sunday□s total = 38 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo

Conditions are very unstable for weeks now, at least here in Europe. I had tuned to the middle of the 20m band and got absolutely nothing (not a trace!) on the SDR listening to IF1 of the TS830S. Even 40m (usually more than busy in the early evenings) showed only a few Italians and Russians running their splattering (multi-?) KW-linears. At 80m things were normal (as normal as they can be on this band...) The higher bands were plain dead.

Update

Got it going and on the air. Major issue with both receive and transit full power, all related to signal levels. Coils L16 and L28 on IF board, and transformer T16 on the PLL would not peak or pass through resonance to produce the RF levels shown in the alignment procedure. It appears the capacitor, internal across the coil, changed value, not allowing the signal levels stated in the alignment procedure which are a must.

Update:

I found Q7 & Q8 both bad. After replacing them VR1 & 2 could now be adjusted and the meter now read S-6 at turn on. The RF gain still had no effect. I traced all possible paths through the AGC and removed Q3, Q5, Q6, and disconnected one side of R108. The last remaining path was to Q2. I removed Q2 and now the meter now read zero at turn on, except for that split second jump. Adjusting the RF gain the meter goes from zero (RF gain CW) to S9+60 (RF gain fully CCW), just like every other rig I have used..

I reinstalled Q3, Q5, & Q6 (I made sure they were put in correctly and no solder shorts), and resoldered the one end of R108 and tested the rig. Again the meter was at zero on power up and went from zero to full scale using the RF gain. Since Q2 is an 3SK73 and that transistor may not be available I did some searching and either a 3N211 (NTE454) or 40673 (NTE222) could be used. I had a couple of NTE222 so I put one in. Upon power up the meter was at zero but it would not move when I adjusted the RF gain. I checked the AGC and it was at over 9 volts. Thinking I had a bad transistor (or I had put it in backwards) I installed the other one and still no meter action at turn on. I looked up the pinouts for both a NTE222 and NTE454 and they are the same so I knew that wasn't an issue. I removed the other transistor and now the meter works fine and is at zero when the rig is powered up (no Q2 is installed). The AGC goes from <1V to 2.6 V while adjusting the RF gain.

Unless I go to eBay and spend a lot more for an 3SK73 I may be at a stopping point. Has anyone dealt with something like this? I know my troubleshooting method is weird but hey - it worked for me. Thanks everyone for your help.

I just obtained a TS-820S from Ebay. I finished setting it up this weekend and it appears to be in good shape. It tunes up on all bands. I do have some questions:

The digital display was not working when I first started using the rig. After about three days of use, the display started working. However, sometimes it turns off. Are dirty contacts the cause? The light on the meter is not working. Is that a hard fix? One of the paddle switch covers is missing. I looked on E BAY and could not find any. Any suggestions where I can find one? In the evenings, I am picking up lots of what I think is RFI. There is significant static on 40 and 80 meters. I have two separate antennas. One is a homemade buddistick and the other a 41 foot end fed wire antenna connected to a 9:1 UNUN. I have an MFJ Deluxe Versa Tuner II (I am able to get the SWR below 1.2:1 on all bands at >100 watts). There is the same amount of RFI on both antennas. Are there any additional steps I can take to deal with the RFI? I will try to join the net this weekend. Thank you in advance for your assistance.

> Mike KS7YSH

That -really- depends on what else is on the existing circuit and the total load you're going to put on it. That said, it is in my opinion just about NEVER a bad idea to have a breaker dedicated to the shack. Makes killing the power for maintenance or upgrades of the shack wiring pretty much painless for the rest of the house, for one thing.

Also it's a good way to ensure that nobody gets across anything they oughtn't. Just throw the breaker and lock the box, and it's as safe as can be.

I have toddlers in the house on a regular basis. Two-year-olds can get into things you wouldn't believe, in unimaginably short amounts of time.

Unless you will be running a lot of equipment and a high power amplifier at the same time, you won't need additional 120VAC 20 amp or 220VAC 20 amp circuits to your ham shack.

Your house breaker panel should have the listning completed, indicating what each breaker protects. If the breaker panel is blank then you should determine what each breaker protects and update the breaker panel listing. That will allow you to know what breaker to throw to turn all power to your ham shack OFF when necessary!! Any additional breakers added, the listng should be updated to show what that bvreaker protects.

Hi David,

You haven't really given us much to go on but here's a start.

For the display you need to do some trouble
shooting. Download the service manual and work
out what signals are required to make the display
work. There are lots of discussions in this group regarding the displays.

The meter lamp is not hard to replace.

For spare parts contact Walter Dilley at the
following email address: walter.dilley@...

You write as if the noise only appears on the
820. If so you need to start an investigation in
your radio. If you get the same noise on all
radios you own then you need to investigate the
noise source - not so easy but there is a lot of
info on the internet to explain how to go about it.

Enjoy your radio

Lou

53441. For Sale RF Sig Gens

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-11-20 14:19:58 UTC
From: wagstw46@...
Topic: 53441 Message: 53441

Hi Folks:

I have upgraded my RF signal generators to an HP8656B and an HP8640B.

I am selling both of my Wavetek 3002 units. These are PLL units and the same RF sig gen that is on Ken Kempski K4EAA's hybrid service bench and I believe same one that Dick Housden W0NTA uses in his restoration of TS530/TS830 rigs. I am offering both here before listing on QTH.Com and/or Ebay.

Unit 1 is in nice cosmetic condition and was refurbed and aligned and calibrated by Dennis McGrew K8IFF who is a Wavetek guru. I am asking $285.00 properly packed and shipped (conus only).

Unit 2 is in good to nice cosmetic condition and functions perfectly about 90% of the time. From time to time its output "unlevels". When this occurs usually if you power it off and let it rest and re-power it locks and works as it should. I have not had time to troubleshoot this intermittent problem. I am asking $225.00 packed and shipped.

Physical size is 13w x 16d x 6h which makes them ideal for the average service bench.

I have operating and service manuals and cal data sheets.

If interested please contact me off the Reflector. Can also call my home phone 269-663-8943.

Terry K9TW

When I spent four years aboard my 36 ft sail boat in the south pacific ocean, my digital display on my Kenwood TS-50 would sometimeloose or only show part of the display. I would put the radio in the galley oven on very low heat and within 2-5 minutes after hooking therig back up, they display returned to normal. You might try a hair dryer on low setting (with radio off). I just restored the display on aGrundig Satellite short wave receiver the same way. Please try at your own risk. Good luck, Rich K8UV

I purchased one of the Wavetek 3002 from Dennis McGrew as Terry said, he is a guru on them, and mine was completely refurbished by him, and they are great signal generators. I did get spoiled for the 21 years of Air Force use of HP8640B signal generators, but I can't afford to have an 8640B sitting on the bench. The Wavetek will do everything the hybrids need, with a signal down to -130dbm which is about .1 microvolts....if your receiver can pick up an intelligible signal at that level ....wow!
Good prices too Terry. 73

Jeff:

My hybrid repair work volume allows me to upgrade test gear from time to time, but you are correct that the Waveteks are all any KW Hybrid owner would ever need to troubleshoot and maintain these radios.

Once you use a synthesized RF sig gen you wont want to go back to an old LC oscillator type. They will work for signal injection/signal tracing, but not good for calibrations alignment work and often have very poor shielding so that low level test signal that you think is coming thru the coax test lead to the receiver front end is really being radiated. I found that out years ago after being pleased with receiver MDS results and then I removed the old Heath sig gen test lead from the SO-239 and I could still hear the tone in the speaker!

Also, the Waveteks size is great for the average bench. I am in the process of revamping my shelves above my bench due to the much larger physical size of the 8640B and the 8656B. This 8640B has new metal gears and new contact fingers and the 8656B is near pristine. I would say at this point I have no need to upgrade beyond this level unless I would get a steal.

Regards Dennis he also stands behind his work and charges peanuts for follow-up cal and repair work on any unit he has sold. I have met him as he traveled in my area and delivered a unit to me and bought a couple of SG-1170U Waveteks that I had as part units (military version of the 3002 units).

Rick

53446. TS-820s brought out of storage

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-11-21 16:43:15 UTC
From: smallrc@...
Topic: 53446 Message: 53446

I brought my TS-820s out of long-term (less than ideal) storage not long ago. It had the typical display and scratchy control issues. After cycling the switches, pots & VFO repeatedly and unplugging & plugging the accessible molex connectors, I left it turned on "cooking" for about two weeks. The display is operating OK now, but the VFO and band switch are still scratchy and jittery, especially the top end of the VFO. I haven't yet used any contact cleaner on the switches & pots. I have used deoxit spray in the past with pretty good results, but I was wondering if a product called "Corrosion X" would be a better choice. Has any one here used both products for a comparison? Is there another product that you would be recommend?

Any suggestions would be appreciated...

tnx es 73,

Kenny, WB0VPS

Kenny,

Your problem appears to be instability in the 820's VFO variable capacitor Frame to Shaft Flex connection causing unstable VFO tuning. I have a video on my website that shows how to clean a variable capacitor's flex shaft to frame connection. I do not have a spare TS-820 VFO so I used a couple of variable capacitors and a Heathkit HW-101 LMO. The video can be viewed by clicking on the following link:

http://w5rkl.com/wp-content/uploads/2015/02/Cleaning-Variable-Capacitor-Flexible-Shaft-to-Frame-connection.wmv

You can also download the video to your computer by right clicking on the above link and select "Save Link As". A window will pop open on your computer, select the location you want to save the video to, then click "Save". The video will download and save to the location you selected under the file name "Cleaning Variable Capacitor Flexible Shaft to Frame connection.wmv". You do not need any special video viewing software, Windows will display the video for you.

The TS-820 service manual can be downloaded from my website at the following link:

http://w5rkl.com/wp-content/uploads/2014/04/ts-820s_service_manual.pdf

Remove the VFO from the TS-820 then remove the VFO's outer metal enclosure. This will allow you to have better access to the VFO's variable capacitor. Be careful so you do not bend any of the variable plates or damage the VFO circuit.

The LMO (VFO) in my Heathkit SB-303 receiver had this same reoccurring unstable tuning problem. I tried cleaning the flex connections many times but after a while it came back. I got tired of that so I removed the LMO from the receiver, thoroughly cleaned the LMO's variable capacitor flex shaft to frame connection, removed all old ball bearing grease, and applied DeoXit L260Ap conductive grease to the shaft bearings. That was over a year ago and the LMO has been stable ever since.

Remove the VFO from the TS-820 then remove the VFO's outer metal enclosure. This will allow you to have better access to the VFO's variable capacitor. Be careful so you do not bend any of the variable plates or damage the VFO circuit.

The LMO (VFO) in my Heathkit SB-303 receiver had this same reoccurring unstable tuning problem. I tried cleaning the flex connections many times but after a while it came back. I got tired of that so I removed the LMO from the receiver, thoroughly cleaned the LMO's variable capacitor flex shaft to frame connection, removed all old ball bearing grease, and applied DeoXit L260Ap conductive grease to the shaft bearings. That was over a year ago and the LMO has been stable ever since.

Kenny,

I use both products and find them both to be effective. I have Corrosion X (hybridrestore.com) in a "dropper" bottle and find it handy to apply with an artists brush to band switch contacts, Molex connectors, etc where the contacts are exposed. Deoxit-5 in a spray can is most useful for hard to reach areas where you can use the spray tube to get at the inside of switches, pots, or hard to reach spaces.

Clint,

I have used the following from ebay and found it satisfactory when properly used:

KENWOOD LIGHT GRAY TRANSCEIVER PAINT TS520 TS820 TS830

Plug this in in the ebay search engine and you'll find it. It's not cheap, though.

I just repainted my 520S with a custom mixed paint from Lowe's. It is a near perfect match and only cost $3.50 for the half pint. I used a self-etching primer in a spray can and rolled the custom paint with a 2" roller and it gave the correct texture and everything. I'm VERY pleased with mine. I just took the side cover in and they put it on their machine and it kicked out the paint automatically. It's a semi-gloss by Valspar.

I use DeoXit D5 sprayed on a Cotton swab. I then lay the cotton swab up next to the shaft and flex fork connection and press down gently on the shaft. I do not press towards the flex fork shaft to frame connection. Pressing down "gently" on the shaft causes the cleaner to "squeeze" out from the cotton swab and flow around the shaft and between the flex fork connection. I then rotate the variable capacitor shaft a number of times throughout it's travel, end to end. I then use canned air found at Walmart's TV/DVD/Cell phone department, to remove the dirt and D5 cleaner residue. It's important to ensure all of the D5 cleaner residue is removed, paying attention to the surrounding components/circuit boards etc. Check the bearing end of the shaft for old dried caked grease. Remove the old caked dried grease, a tooth pick works to remove the old dried caked grease from the bearings, then apply light weight grease. I use DeoXit L260Ap conductive grease applied using a "flat" tooth pick found at your local grocery store. Make sure when applying the L260Ap grease that none of the grease falls onto and embeds in any of the variable capacitor plates, fixed and/or variable, as the grease is conductive. Once completed, thoroughly check your work for remnants of contact cleaner, remove all cleaner residue you find. Then thoroughly check for remnants of conductive grease in places it's not suppose to be, the grease is conductive, and again remove any conductive grease you find that's in areas it should not be. Install the VFO cover back onto the VFO, install the VFO back into the transceiver, you're done.

I have a video on my website, click on the following link, that shows how to clean the flex fork shaft to frame connection on a variable capacitor. The capacitors shown in the video are not the same as the variable capacitor in the TS-820 VFO but the flex fork shaft to frame connection is the same as the flex fork shaft to frame connection in the TS-820 and other VFO variable capacitors.

http://w5rkl.com/wp-content/uploads/2015/02/Cleaning-Variable-Capacitor-Flexible-Shaft-to-Frame-connection.wmv

There are 2 flex fork shaft to frame connections in the TS-820 VFO variable capacitor, one on each end of the variable capacitor shaft. Both ends must be cleaned.

I have a Heathkit SB-303 solid state ham band receiver. Nice receiver but it had the same "reoccurring" unstable tuning. The SB-303 LMO (VFO) variable capacitor has only one flex fork shaft to frame connection in the LMO (VFO) variable capacitor. I removed the LMO, cleaning both ends of the shaft, removed all the old dried up bearing grease, then after cleaning the flex fork connection, I then applied DeoXit L260Ap conductive grease to the bearing end of the shaft. This solved the reoccurring unstable LMO (VFO) tuning, that has been over a year ago.

The LMO tuning is still very stable.

I paint the KW hybrid cabinets I have owned (TS-520S and TS-820S) with what sailors refer to as "Haze Gray". It's a light gray color and looks very nice. A couple of coats are applied and allowed to dry thoroughly. I then apply 2 coats of clear coat. Looks very nice.

What ever color you chose is entirely up to you.

I did pretty much the same thing on my TS520 - took the side cover off and got them to match it at the local hardware store with a semi-gloss paint. I sprayed the cover using a fairly thick paint mix, (so it spatters a bit when it comes out) and the effect is just like the original. I think the idea of using the 2 inch roller might be easier though.

Cheers,
Peter - VK2AN

53466. Hybrid Net Update (November 22, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-11-22 18:37:42 UTC
From: Mark Gilger
Topic: 53466 Message: 53466

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by Jimmy, WB2KNR.
There were 26 stations checking in under good
band conditions. We had 2 new station, K3MYK & KD2BJY.

We had the following number of radios checking in.

2 running TS-520(x)
4 running TS-530(x)
2 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
1 running 599 twins
0 running TS-900

Jimmy was running his TS-520 and Heath SB220.

The Sunday net was run by me, WB0IQK. There were
8 stations checking in under poor
conditions. The ARRL SS contest was going on
and really had a lot of QRM at my location.

We had the following number of radios checking in.

3 running TS-520(x)
0 running TS-530(x)
1 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-830s + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and

TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 □ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins
Nov. 2014 □ Oct 2015 Saturdays total 962 check-ins, Sunday total 669 check-ins

November 2015, Saturday□s net total = 66,
Sunday□s total = 46 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

53471. TS-520S for sale

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-11-23 16:13:56 UTC
From: Mike W5RKL
Topic: 53471 Message: 53471

I have a TS-520S I have up for sale. It has a problem that prevents transmitting.

The problem is the 520 has an intermittent erratic final amplifier ALC and IP which, in receive, affects the S meter and can be heard in receive as static with or without an antenna connected. The problem is not the final tubes or the driver tube, I've changed them. When the problem doesn't occur the radio has normal 60ma idling current and both receive and transmit, sideband and CW work. The radio only has the side band filter. The left side cover plate is missing, it was missing when I bought the radio I just didn't look for a replacement. The 12 pin Jones power cable is wire with a 3 wire grounded plug. The fuse holder has the correct 6 amp fuse. All dial and meter lamps work. VFO tunes smooth, and the Remote VFO socket has the original factory jumper plug, not a jumper wire.

The knobs are all original. The SEND switch lever is Gray, not Black as it normally would be, it was missing but the seller included a gray lever. The SEND switch does work as it should. The leather handle is in excellent condition, no broken/loose threads. The internal speaker is mounted on the top cover but doesn't have the cable socket mounted to the speaker nor the internal speaker cable to the rear Speaker socket. The rear panel Speaker socket works fine with an external 8 ohm speaker.

I added an IF output RCA socket on the rear panel that feeds the 3.395Mhz IF signal to a Kenwood SM-220 with the BS5 adapter or to a Heathkit HO-13 or SB-620 Ham Scan/Scan Analyzer set to operate at 3.395Mhz IF signal. I have tested the IF output with my Heathkit HO-13 which is set to operate at 3.395Mhz, works great.

I simply do not have the time to mess with it. I'm asking $125 plus shipping. If interested contact me off group.

Subject: [TS-520_820_530_830] SSB Power Output

Picked up a TS-830 so I would have a rig for our local "Tube Net" and need to be able to reduce output power when using on phone.
Don't really like idea of reducing microphone gain.
Looking for suggestions.
I Use a QSK Amp and it does not have any form of ALC.

Lew,

The following link to my website is a circuit I built that will work
well in applying a variable negative DC voltage from the 9 volt battery
to the TS-830's REMOTE DIN socket REMOTE ALC to pin 6 (RAL) and ground.

http://w5rkl.com/wp-content/uploads/2015/02/Kenwood-Hybrid-QRP-circuit1.pdf

If you are not into building circuits, the following link from my
website is a much simpler circuit that will perform the same thing.

http://w5rkl.com/wp-content/uploads/2015/02/TS-520S-QRP.pdf

Note the caption shown in the file's picture states

"TS-520 Modification for QRP operation on SSB"

The circuit shown in the file will work just as well in the TS-830.
Change the connections to the 8 pin "Ancillary" socket shown in the file
to the TS-830's rear panel 7 pin REMOTE DIN socket. Pin 6 in both
sockets is the "RAL" (Remote ALC) connection, a "negative DC voltage"
from an external linear amplifier to control the transceiver's power output.

The term "Ancillary" actually refers to the "REMOTE" 8 pin socket on the
rear of the TS-520 series transceivers.

You can "fudge" the ALC with a battery and resistor as per the other reply but the trouble with ALC is you can get overshoot and cook a solid state amp in milliseconds. The safest way is to use a hybrid attenuator - 50 Ohm ones are available in different values on Ebay.

I use a 10db one to drive my Mosfet linear - reduces the power from 100W to 10W and no chance of overshoot. You need to mount it on a good heatsink though.

Cheers,

Peter - VK2AN

This reduces the power into the linear. See picture. The long coax goes to the trx relay. I use it on my 830s and AL-811. Works great

The radio has about 1-10 watts output on 160 through 40, the rest of the bands not even a watt out. Checked voltages on the driver and finals and all were good. Checked the drive level through the drive chain and approximately 40V p-p at the control grids of the finals. In receive almost all bands show an S-9 signal level with the calibrator on and the drive peaked. I have not done a coil pack alignment due to the signal level on receive. Changed out the finals and driver tubes with know good ones - no change in level.

I'm about to pull and clean the antenna relay followed by a drive coil alignment. One thing I did notice that with the load CCW there is about 10W out on 40. Any other position there is maybe a watt or so out. Could a bad (open or high resistance) set of transmit relay contacts be causing this?

Unsure if this is a new problem with sudden onset of no power output.
Give the relay on IF board a tap see if there is any change, most prob wont be.
Check all the molex connectors are seated correctly, being very careful as not to cause another issue. Try giving the bias pot and rear panel a couple of turns in case grit has built up. Finally check the tif voltages. Unsure of your test equip situation and experience.

I always go for minor typical problems first and gradually build up to deeper fault finding. This helps you get a good understanding of you radio and if inexperienced will help build knowledge.

Also forgot to mention, look inside the PA cage with power off and disconnected, make sure no hv.
Between the 2 x 6146b tubes, have a look at where the tube caps connect. There is a type 1 rf cap that commonly cracks due to heat. Also look between base of tubes where you will find a green choke, looks like a resistor. If that has darkened or cracked this may be your issue. Look at men's, k4eaa webpage and you will see photo.

New ham. Given a TS-520SE. I think I have read Every web post on this unit. I have TX, weak RX. I have cleaned all contacts, tightened boards, cleaned relay (was a little noisy when tapped).

Have not tried alignment. I did see a tech bulletin for shorting band select and the zener replacement, but want to try the "low hanging fruit" first to not cause more trouble.

I have extensive basic electronic experience, not much on RF.

40v P-P RF voltage is very low RF drive unless you meant to type 40v RMS?

Around 47 rms RF volts at control grids or around 133v P-P is minimum for FSD ALC indication.

What does the TX Level Diagram in the Service Manual tell you about the RF voltage at DRV and Control Grids of 6146 Finals?

What do you see at TP-4?

What are you using to measure the RF drive and on what band? Suggest you start measurements at 7.2mhz to minimize capacitance effect of your probe even though the TX Level Diagrams are run around 14.2mhz.

If you meant 40v RMS then pull the Ant TR relay and measure and clean its NO contacts. One other problem can be a bad RF Plate Choke and/or a bad RF bypass cap at its base. Look for discoloration on the choke windings and look for darkening and/or cracking on the bypass cap. On rare occasions the Plate block/coupling cap can be bad.

Signal level on Receive has nothing to do with the Drive coil alignment. Pretty common for the Drive coils not to be optimized for the Mixer coil positions in RX mode. I have a white paper on my website explaining why KW service manual tells you to "receive the marker" in Step 14 when adjusting the Drive coils.

Topic: 53497 Message: 53497

Good evening,

The meter lamps on my TS820S were not working. However, the VFO dial lamp is working. I replaced the meter lamps with ones I bought from K4EAA. I installed the new lamps, but they also do not work. Any advice on additional steps I should take? I don't want to break anything....

Thanks,

David Richer,
WB6VGO

53498. TS-530 no Rx or VFO display

Hi all,

LOVE the Kenwood Hybrid Radios!! This is my FIRST HF rig.

Was working FLAWLESSLY for the first few months.

THEN, today I turned her on (or attempted to) and NOTHING.

NO Rx, No digital display, the Meter back light was on and the VFO red indicator light above the VFO display was faintly ON.

What is wrong with my machine???? Just new to HF and this is my window to the HF world.

I have a soldering Iron and Digital multi-meter.
Not afraid to get my hands dirty. (what else do I have to lose at this point?)

HELP!!!!

Thanx in advance.

KD9BWU -Extra

Mike

Hi David,

Yes, get a volt meter and take some measurements.
Is there volts at the point where you terminated
the wires? Are your globes ok - continuity?

Lou

I forgot to suggest that you can run Driver stage test (see messages like 49369, 52410 and many others).

Also, if very careful can run 6146 static or DC emission test. With either test keep key down time very short (around 5 seconds) and NEVER allow any color to be seen on the 6146 plates (no dull orange whatsoever).

For DC emissions testing it is same as setting zero signal plate current to 60ma in LSB or USB mode only instead of stopping at 60ma continue lowering the bias voltage until you see 300ma indicated Ip. Hold there for no more than about 5 seconds and should see no drift lower in plate current.

This is not a routine test that anyone should be performing. Your rig is your Dynamic tester under RF drive conditions.

If nervous about doing this test substituting known good spare final tubes is better idea. Everyone should keep a set of spare finals. NOS 6146Ws are a good choice.

TS-830s the meter lamp intermittently goes out, tap the top of the rig and it comes on and stays until I turn the rig off. Not every time I fire up the rig, maybe just 1 out of 5 times. Would love to track it down but taking the cover off moves it to come on, hard to track down if it's working.

Fred:

The lamps are powered from a phenolic terminal strip on bottom side of the chassis near the rear of the VFO shield can. Becareful as not too far from 900VDC on HV filter caps.

Very easy to monitor lamp supply voltage here and to push/pull on the red lamp lead wires terminated (soldered) at this terminal strip as a starting point. The orange AC supply line leaves the terminal strip and goes to the hot side of the Heater switch. Not common for it to be bad solder connection or broken off at Heater switch.

Could be a bad filament in the lamp that is making and breaking with vibration. Remove top cover and tap on the lamp in its silicone holder.

Hopefully this will be the toughest intermittent that you face. I cant tell you that they can get a bit more challenging.

53507. Taming TS-820 VFO drift

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-11-30 02:53:42 UTC
From: kb8tl@...
Topic: 53507 Message: 53507

I thought I'd share my experience with a near junker TS-820 I picked up recently as a project radio. It had a plethora of problems but the most irritating was VFO drift. When I turned the rig on, it would drift a couple of hundred Hz over the course of the first several minutes and gradually settle down after maybe 30 minutes. Now my old Drake R-4B has no such problem and my TS-830 likewise has no such drift, both with analog VFOs.
So, I waded into the VFO's innards and to make a long story short, I did all the usual cleaning, re-soldering, tightening, etc. to no avail. So, start swapping parts. The oscillator transistor is a 3SK22 dual gate MOSFET of which I have none in the junk boxes. Oh a hunch, I consult the TS-830 schematic and I see that the circuits are virtually identical EXCEPT it uses a single gate FET and the source resistor is 4.7k vs 100 Ohms in the 820 VFO. So, I had on hand 2N5486 JFETs and I make both changes to match the 830 circuit and success!!! The 820's VFO has virtually zero drift now.
So I think two possibilities:
1) The original 3SK22 was defective and somehow causing the drifting. Not too sure about this as it was consistent on every warmup.
2) The orginal 100 Ohm resistor was passing 2 mA through the 3SK22, causing heating and the drift was normal. About 18 mW of DC dissipation in the MOSFET. So now with a 4.7 k source resistor, there should be much lower DC current flow. About 4 mW from the DC values vs 18 mW previously.

So, you can use a 2N5486 JFET in the 820 VFO if the original 3SK22 MOSFET fails and the VFO still has more than enough RF output to allow correct adjustment of output level at service manual step 2.11

Good morning Bob, I don't think my 820 would ever quit drifting! I usually turn it on the night before and it is not too bad. If I just leave it on all the time it still has a very slow drift. I thought about a VFO stabilizer of some sort. I have built and installed the X-Lock on other radios and they do work well. Do you know how much it drifts after 30 minutes or so?

Thanks
Lynn kb

Lynn, I haven't fully measured it yet but a cursory check shows about 200 Hz (per the display) after an hour and that is about where it stops. It really is night and day better than it was.
I'll try it tomorrow from a cold start and try to note the freq drift vs 30 minute intervals.
Bob

If your finger is even very close to the metal shaft of a screwdriver and you touch the plate caps of the final tubes with the radio powered up (not even transmitting) ,The reason you will be sorry is the next doctor who examines you will be the Medical Examiner or Coroner. The extrreme muscle contraction of your arm muscles will probably drive the screwdriver, still firmly in your grip, through your eye and into your brain. Brent,

Your brief posts from your phone do not
adequately describe your situation - we are all
guessing at your meaning. As Bob and others have
said if you are talking about the 6146's then the
cap is not the grid but the anode and there is
high voltage on the caps - around 900 volts. I
would strongly you advise against probing around
inside a powered up radio with anything
conductive. At best you could cause more damage
to your radio, at worst . . . . .

From: wagstw46@...
Topic: 53492 Message: 53515

As several have mentioned shorting the anode cap to the PA cage sheet metal with a screw driver is not "good safety practice" and has been addressed in messages such as 46783, 43226 and others. Disregard this practice that is posted in the Files section by a well intentioned, but misguided member.

Once again here is summary of why not:

1. The main RF plate choke and the small VHF choke at its base are small gauge windings. Not a good idea to dump this joules level thru these windings and stress them. More importantly if the winding should be open and you obtain no arc/pop when touching screwdriver it could fool you in to thinking that the HV capacitor bank is discharged when it is not. Better place to ground at is the positive terminal of the capacitor stack.
2. My radio and my customers radios are not welding machines. Any time you use this practice there will be arcing and pitting and transfer of metal take place. We all have different quality standards.
3. There is a phenomenon with electrolytic capacitors called "dielectric relaxation". After "popping" the capacitor the charge voltage will begin to climb back up and can rise to pretty high level. You must hard ground for several RC time constants to address this action. There is a You Tube video that demonstrates this on a low voltage electrolytic.
4. Better practice is to make a high quality grounding jumper with a current limiting resistor in series and apply it at the capacitor bank and leave it affixed for awhile. You do this after downpowering and unplugging the line cord and waiting a few minutes to allow the bleeders to do their job. Also, you must make a contact voltage measurement with a known good voltmeter before barehand touching.
5. Remember that grounding the 900vdc HV caps (anode or B+ supply for the 6146 tubes) does nothing to discharge the 300 and 210 power supplies. Poking around on the Rect Board can give you a nice bite. Very common for R9 330K bleeder on the 300 supply to go very high or open and the 22uf caps to retain full charge for a surprisingly long time.

OK all thank you for the warnings. I understand that that caps are not grid caps. I knew that but have been dealing with grounded grid configurations for a while so I just slipped on terminology.
So here is detail:

I got the rig and it received but had no drive/output, No bias. I thought I might check the power supply and rectifier board so I removed the cover,blew the 1/2" (1.3cm) of dust from the inside and inspected the finals and driver. They probably were originals (2001's) but I checked all of PS voltages and rectifier board since I was there. All were good . I ordered new tubes, and replaced them. Now I'm no green horn so I understand the perils of HV caps and shorted the caps to chassis (twice) and then clipped a lead from them to chassis for added measure. When I installed the new tubes I flipped the switch to check things out and had forgotten that the lead was still clipped to chassis. The rig immediately blew the 4 amp fuse and I slapped my forehead and kicked myself in the ass. I replaced the fuse, flipped the switch and she came to life but this time no receive,good bias but still no drive/power. The VFO light is on and the SG switch is in the correct position.

I started looking for loose connections and found that the WWV/JJY switch had 2 wires loose. I checked the switch and it functioned properly. I posted here for advise on which wire went where on the switch. When no one responded I traced the schematic and the wires for the switch and am very comfortable they are correct. However still no Rx or Rx. When the WWV switch is on, the S meter rises but no WWV signal. My question about the grounding to chassis was me wondering if I might have blown something by grounding to chassis instead of a ground isolated from the radio. I got this response " TURN OFF THE POWER BEFORE GROUNDING THEM.
>
>>>
>>> OR YOU WILL BE SORRY"

Now I'm thinking that because I turned on the rig with the caps grounded, I might have damaged something.

I'm just at an impasse and frustrated. I don't have an idea of where to start.

Hope this helps.

Bob and others have said if you are talking about the 6146's then the cap is not the grid but the anode and there is high voltage on the caps - around 900 volts. I would strongly you advise against probing around inside a powered up radio with anything conductive. At best you could cause more damage to your radio, at worst . . . . .

Thank you Terry. That is why I made a jumper as you described actually and placed it to chassis ground to keep them from building back up and biting me. Now if someone could just give me some kind of starting point. I want to start looking for how to repair my radio. That is the whole intention of my post. Not that I don't appreciate the safety lesson I do. I'm not being critical of you in particular, however, it seems that every time I ask a question on this forum everybody has an opinion about safety and what the grid caps really are, I didn't include my name on my post, and that I'm posting from my phone,but no one has given me one iota of technical information about how to fix my radio I thought that is why I joined this form in the first place.

> As several have mentioned shorting the anode cap to the PA cage sheet metal with a screw driver is not "good safety practice" and has been addressed in messages such as 46783, 43226 and others. Disregard this practice that is posted in the Files section by a well intentioned, but misguided member.
>
>
> Once again here is summary of why not:
>
> 1. The main RF plate choke and the small VHF choke at its base are small gauge windings. Not a good idea to dump this joules level thru these windings and stress them. More importantly if the winding should be open and you obtain no arc/pop when touching screwdriver it could fool you in to thinking that the HV capacitor bank is discharged when it is not. Better place to ground at is the positive terminal of the capacitor stack.
> 2. My radio and my customers radios are not welding machines. Any time you use this practice there will be arcing and pitting and transfer of metal take place. We all have different quality standards.
> 3. There is a phenomenon with electrolytic capacitors called "dielectric relaxation". After "popping" the capacitor the charge voltage will begin to climb back up and can rise to pretty high level. You must hard ground for several RC time constants to address this action. There is a You Tube video that demonstrates this on a low voltage electrolytic.
> 4. Better practice is to make a high quality grounding jumper with a current limiting resistor in series and apply it at the capacitor bank and leave it affixed for awhile. You do this after downpowering and unplugging the line cord and waiting a few minutes to allow the bleeders to do their job. Also, you must make a contact voltage measurement with a known good voltmeter before barehand touching.
> 5. Remember that grounding the 900vdc HV caps (anode or B+ supply for the 6146 tubes) does nothing to discharge the 300 and 210 power supplies. Poking around on the Rect Board can give you a nice bite. Very common for R9 330K bleeder on the 300 supply to go very high

or open and the 22uf caps to retain full charge for a surprisingly long time.

We do not know you. We dont know your knowledge level or your experience level. When someone doesnt use the correct technical terminology in a post we have to assume they dont have adequate knowledge or experience. Disrespect is never intended. Our very first moral obligation has to be dispensing personal safety counsel. Pretty hard to guard against rattle snakes if you dont know where they are at. We cant assume you have ever been under the hood of a KW hybrid.

Giving troubleshooting advice by this medium is difficult at best and is fraught with peril. Peril for those receiving the advice and peril to those giving it. No one wants to see anyone get killed and doesnt want to get a letter from the members family stating that a civil suit is being brought against them for directing them with no regard for their knowledge or experience level ie negligence.

All we can do is tell. We cant demonstrate. We cant observe you and we cant provide any kind of feedback or coaching.

I make no apology for assuming you have little experience and putting safety first.

As for troubleshooting no Rx I assume you have tried the Marker with no signal heard?

Troubleshooting receiver can be done via SIgnal injection and Signal Tracing method. Can start at the RF front end and work toward Speaker or start at Audio Amp and work back toward the front end. Do you have an RF signal generator?

Do you have CW side tone? If you clip test lead to wiper of Audio gain pot and touch it with your finger do you get hum in speaker? If so then you know Audio stage is good.

Usually can inject 50uv or -73dBM into the SO-239 (level not critical but use enough to give decent S meter indication and tone in speaker) and look for it along the path thru the Ant TR relay nc contacts, RF attenuator , molex connectors etc to the RF board.

For a quick check do you have good regulated 9VDC and what is RF-1? If you turn RF gain pot full CCW does S meter peg full scale?

Do you have VCO signal or HET osc signal? These provide the LO to both Rx and Tx Mixers depenging on the rig.

Far too many keystrokes required to tell you step by step how to troubleshoot no RX. If you are looking for common failures there are a few like bad/dirty molex connectors, bad/dirty RL-1 aux control relay contacts, bad L41 ant step up transformer on 530/830 rf board etc. Frankly I have forgotten which rig we are talking about so cant offer any more quick check items.

Another problem is we do not know what kind of test equipment you have or your knowledge of how to use it.

If you don't have the needed test equipment you can buy it or find someone to service your radio for you.

Use a voltmeter with sufficient range and measure at the pins of the HV caps. Clip the ground lead of the voltmeter to the chassis, switch the rig on and measure at both HV caps. The short wire between the "+" pin of one cap and the "-" pin of the other should show around 400V, the "+"-pin of other one should measure 800-850V.

The voltmeter must be good for 1KV voltage! This is not the place to play around with a $3 chinese toy...

This measurement shows that if you have HV voltage at the power supply.

Hi Bob, Can you write a program to record the 9 vdc supply? I have seen suggestions to replace a zener regulated supply with the newer 3 pin regulator. Some think these provide better regulation. Some time ago I did just that with a 9 vdc supply and it worked well. You might check out the X-Lock website and the different ideas.

Hi, everyone,

I posted this to the TS-590 group, and would appreciate comments from Kenwood users in general regarding their experience with linear amplifiers. If there are any special settings in any of the rigs that help with performance, it would be great to include comments about that, as well - thanks!

Here is my original post earlier today:

I would like to purchase a linear amp to put in line between my TS-590S and Hygain vertical 640 on the roof. I mostly do CW, but also a fair amount of SSB and digital modes. I'm chasing DX and would like to bust a few more pile ups than I currently do.

I do a lot of band switching, and I don't have a lot of antennas, so keying into the wrong antenna is not a concern (I hope not famous last words :) - so I most likely will go with a solid state amp, with a built in tuner. I would like to be able to switch bands and have the amp automatically switch and tune. (My antenna has SWRs below 2.0 for all 40,30,20,15,12, and 5 M without a tuner, and well below 1.5 for most of those bands, the last time I checked).

Also, I plan on purchasing a linear amp that can put out 1 kW.

I'm very interested in hearing about experiences and related comments.

Thanks!

73 de KG9ML Mike

I RAN MY TS520 (no S) into a Henry 2k and recall running about 800W output on 10M SSB. I would find the band dead and after a few CQs I woud usually get a reply. After ending the QSO (sometimes a string of QSOs)_I would tune around again and hear a bunch of QSOs going on on the band. My radio is Ham Radio...CW is Real Radio 73, John...K8JD

Moderators, please remove me from this group. I came here seeking knowledge and ended up with the same kind of crap one gets from a local ham club. A bunch of guys who know a lot but refuse to teach others. Instead of safe, constructive elmering, I get smug, arrogant know-it-alls that provide belittling, holier-than-thou criticism. This is the kind of stuff that drives people who have a desire to learn (life long learners) away from the hobby. If I taught my students in this manner they would hate school and learn nothing. You guys should know better.

Hi Mike,

I did some tests using my home made Mosfet linear amp using a TS520S. I found it worked fine but had significant issues with ALC overshoot. As solid state amps can be destroyed in a matter of milliseconds by significant overdrive (unlike tube amps), I have concluded that the only safe way to drive a SS linear with the TS is NOT to use ALC, but to use a hybrid attenuator on the input of the amp to drop the input to a safe level.

Please note that my amp only requires 10W input for full 1.4KW out. Some commercial amps may already have attenuators on the input - you may need to check.

Cheers,
Peter - VK2AN

Hello All,

I have written to both Terry and Lou privately about this thread.

Here I will only say that if the objective was to be rid of this fellow, it
was achieved efficiently. I hope we can return to more civil discourse.
I hope that if any of you have a problem with me, you will address me
either in a PM or directly here on the forum.

Best Regards,

While I had my TS-820's VFO out and was running it on my variable DC supply, I tried varying the Voltage and it did shift the frequency a bit but if was on the order of 10s of Hertz for a +- 1 Volt change. I think much ado is being made of the 9 Volt supply causing trouble. Perhaps it can make small jumps in frequency if the Voltage is unstable, but I would not call a 1 Volt change small. I've completed my time vs frequency drift data collections on a TS-830, modified VFO TS-820 and for jollies a Drake R-4B. The R-4B was by far the least drifty! I'm posting a Word doc with the results to the files area (as soon as I figure out how).

Hi All,

I'm sorry for the way I behaved and I can totally
understand why Brent got upset. My post to the
group was in error and was meant to be private.
Regardless of what I thought of him I should not
have made public comment. I should have either
shut up or contacted him directly off forum to
discuss my thoughts. No one needs to be talked
about in public the way I did about Brent.

Please don't bring Terry into this, he was not
even aware I was going to send the post.

Sorry everyone

Lou

To Joe wb7uqu, and to Terry K9TW, and to many others on this listserver-
don't loose any sleep over this guy (or lady, if such be the case). I
think the advice that was offered to assist with this ham's "grounding
grid caps" was on the money from the start, and there's no reason why
he/she should have taken any offense. I know that it must have taken a
lot of time to generate the responses that were proferred to him/her-
certainly, I suspect, a lot less than the time that he/she took to
generate the originating email(s).

You all take care and hang in there.

To all group members,
Sometimes it's unfortunate that messages accidentally end up at the wrong place, things happen. I cast no blame. I try and not interfere if a "conversation" stays within the group policy limits, but there were many scary questions being asked by the now gone person. I wish him well. As we all know, there is some inherent danger when working on these and other rigs, and if you're not careful , your XYL will be putting an ad in the paper to sell your stuff. It's SAFETY FIRST here...whether you like it or not. I also know it's frustrating trying to help someone who doesn't have a clue, and wants to be spoon fed every step, or has absolutely no testing equipment, or basic electronic knowledge. We don't mind anyone asking questions...but you have to help us...help you! I am not an expert on these rigs...far from it, and I still marvel at the knowledge base contained in this group.
So, let's all move on...and be careful what we say....oh...I'm not going to loose sleep over this...I've been doing this too long to let that get to me.Ya just can't make everyone happy...all the time.

But remember: SAFETY FIRST...or it maybe your last.....
I now return you to your regular programming....

Joe:

I am sorry that he left and any part I may have had in that action. I try very hard to help members on and off this forum in between my bench time and make no apology to this chap.

He clearly had a high opinion of himself that was not warranted. After lecturing us about his safe work practice and technical knowledge another person described how to measure the voltage at the HV caps to validate that they were discharged and his very next question was did he need to remove the final tubes to make that measurement. At that point we knew we were facing a lot of work.

When someone gets mad about a safety brief I am pretty much finished with them and make no apology.

The other problem is he is representative of how many people "learn" today. Sadly today many people simply want the answer which they are use to getting instantly via Goggle. When he didnt get the simple answer he was looking for he was very frustrated.

I cant imagine being a new ham and buying a KW hybrid as first rig and unpacking it and finding it doesnt work. It has to be a very overwhelming task and majority have no idea how complex it is and how silly the question posed here is .....My receiver doesnt work where should I look? Instead of wearing your heart on your sleeve it would be nice if a person would show a little understanding and appreciation for the amount of time commitment it takes to answer a question like that on a keyboard.

So if other members are disappointed in me that is fine. I am far too busy to worry about "disrepecting" anyone. We live in a PC world today with people easily getting their feelings hurt pretty much daily who have no clue that the degree of respect you get is earned. Thank God our fathers and grandfathers were made of tougher stuff.

I will continue to freely share my knowledge and experience when I can, but will not "baby" anyone.

My feeling is we have a lot younger new people taking an interest in Ham Radio.

But when they look at the cost of NEW, MODERN RICEBOXES they CHOKE!

Then they go to eBay and find something like a KW Hybrid. They buy it having no idea what they are getting into. Then they end up in a place like this looking for help.

I guess we need to find a way to politely tell them they are over their head. Then recommend someone like Terry to fix it for them.

Another thing they find out about is their HOA. They cannot put up a decent antenna. I KNOW ALL ABOUT THAT PROBLEM!

I went to Electronics School (USAF) in the 1950. One of the first things we about was HIGH VOLYAGE. Everything had high voltage in those days.

Hi Folks,

I'm new here and I wasn't going to post, but I can't help it. I read everything here because it's a great learning tool. I read and re-read all the questions and answers regarding this issue. I simply don't see the reason for someone to have been insulted.

It never ceases to amaze me the amount of time and patients Terry and others put in trying to help folks. Doing it with a keyboard has to be very frustrating. I've seen countless times where many hours were spent trying to help someone and all they have gotten in return was a quick, "OK...Thanks." Now they are scolded for trying to keep someone safe.

I would like to say sincerely, "THANKS SO MUCH for the help you've given me and others. If you think I might get myself hurt because you suspect that I might be doing something dangerous, PLEASE LET ME KNOW!!"

I'm aware that often in an email, you're not able to read someone's body language and words can easily be taken wrong. To the fellow who left, I think you should come back and this whole thing should be put to rest.

Now, in large part from the help I've gotten here, I'm going to my shack with a cup of coffee and energizing my CORRECTLY ALIGNED AND WORKING TS-830s.

Best to All,
Kevin - N2FLP

Where have we wandered, out in the land of the Internet?

If you have a question to the group about these vintage rigs, why not put a geographic reference in your post? While some of the answers are pretty straightforward, sometimes you just need to SHOW what you are doing. There are many good ops willing to lend a hand..or simply point an educated finger..that can make a fix much more relevant and more time efficient.

With call signs no longer locked into a specific area...you might find a "1" call living on the west coast of the US, or a "6" call in New England. Valuable experience might literally be in your particular town.

If you are confortable, just pop your city or state after your call sign when you wrap up your post. It might well speed up the repair, answer an operating question, and may just create a new friendship.

Happy Holidays to all, wherever you live and whatever your beliefs.

Paul,

Did you check to ensure the HEATER switch is set to ON? If you TS-520 is the "SE" model then there will be no HEATER switch. The HEATER switch was eliminated in the SE model.

You didn't state whether the meter and dial lamps are lit. If the lamps are lit but the tube filaments are not lit AC voltage at the final amp unit "14" terminal and the RF unit "H" terminal, you should see approx 12.4VAC.

You can't service/troubleshoot your TS-520 KW hybrid without the service and operator manuals. I have them on my website plus a high resolution schematic.

I have ran into the same problem with my TS-830 as I did loose my filament power. You might want to check to make sure that the filament on/off switch is working correctly.

Topic: 53548 Message: 53548

I have a TS520S here that has a 27mhz crystal on the Aux position and covers 27.000 - 27.500 which I assume was a very common mod. I want to remove the 27mhz xtal as it is illegal over here in Australia and for the life of me, I cant find the aux position crystal location. I searched the service manual and it indicates that it should be on board x44-1160 but I cant see any added xtals on there. If you have any insight to where the aux crystal position is on the TS520S, it would be a great time saver.
My direct email is brenton@posnav.com.au mailto:brenton@posnav.com.au and would love to hear from you or anyone who has any clues to why I am going blind. haha
Cheers
Brenton

Hi all,
Thanks for your help. I have been away and also working on the TS530 :- After all these band changing tests, the band switch shaft decided to break. Not really a surprise, with the help of K4EAA's site and supply it could be repaired. - I decided to replace then Q14 4011 gates on counter board to check if it could make ABCD output from counter board alive again. The answer is YES : big step ahead. RX and display are working on some bands now :1,5 and 3,5 are OK. 7 is still dead (no RX and no display). On the other bands the display is there but 0.5MHz lower than it should be. The actual RX frequency looks 0.5MHz higher than it should be.

So still work left, but higher spirit and trails to explore. Your ideas would be appreciated.

Topic: 53548 Message: 53551

Hi Brenton,

The AUX crystal location is right next to L5 (21MHz) on the OSC coil unit (X44-1160-00). It may be obscured by one of the crystals near the top of the board - it's at right angles to the rest of them. Alternately, the wrong crystal might be in the 29MHz position and the person that did the mod may have added jumpers to the switch to try and hide their tracks.

I had to replace the 29MHz band crystal (X8) in my TS520S. A previous owner had replaced the original crystal with one to suit the 27MHz band. As luck would have it the crystal is right underneath the band switch and probably the most difficult one of the lot to access. Looking at the board layout and the service manual it seemed to me that it's quite a job to remove the OSC COIL board just to replace the crystal.

I decided to try and replace the crystal without removing the OSC COIL board and found a method that seems easier than the one suggested in the service manual.

I removed the metal shield next to the OSC COIL board and disconnected the shaft coupler for the band switch then pulled the shaft forward until I could get to the solder connections on the OSC COIL board. ** Make sure you don't rotate any of the switch wafers** I un-soldered the old crystal and pushed the pins through until the crystal was free of the board.

I cut a small piece of heatshrink to go around the new crystal. Under the heatshrink I stuck a few inches of tinned copper wire that I bent in an "L" shape to allow me to feed the crystal under the band switch and poke it's wires through the board. It took about three minutes to get the new crystal soldered in place. Once the crystal was soldered in place all I had to do was slide the wire out from under the heatshrink and the job was done. The heatshrink remained on the crystal but it's so small you can't even see it under the band switch. I pushed the band switch shaft back in and replaced the shield and the hard work was done.

After a coil pack adjustment the radio is as good
as new and I'm really happy with the results.

53552. Hybrid Net Update (December 6, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-12-07 01:30:59 UTC
From: Mark Gilger
Topic: 53552 Message: 53552

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by me, WB0IQK. There
were 23 stations checking in under good band
conditions. We had 1 new station, KB8TL.

We had the following number of radios checking in.

3 running TS-520(x)
3 running TS-530(x)
5 running TS-820(x)
6 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-830s + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
17 stations checking in under good
conditions. We had 7 new station checking in,
KG5HAT, KJ4UGE, N5JUM, W5EBB, K0GIG, KK4PTC, and KI4RCA.

We had the following number of radios checking in.

6 running TS-520(x)
6 running TS-530(x)
0 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-520s + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and

TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 □ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins
Nov. 2014 □ Oct 2015 Saturdays total 962 check-ins, Sunday total 669 check-ins

November 2015, Saturday□s net total = 66, Sunday□s total = 46
December 2015, Saturday□s net total = 23, Sunday□s total = 17 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

73's,
Mark, WB0IQK

Paul,

Assuming the 2 meter lamps and the single dial lamp are lit and the
HEATER switch is turned ON, measure the AC voltage at the RF Unit and
Final Unit's "H" terminals, you should see approximately 12VAC.

If the AC voltage is not there then there's an open between the 2 "H"
terminals and the HEATER switch or the HEATER switch is bad.

The dial lamps are between the HEATER switch and the power transformer's
secondary winding "12.4" terminal so the HEATER switch has no control
over the dial and meter lamps.

Hi Kenwood members,

I like to change some crystals behind the HET unit of my TS700 transceiver.

Those are from user manual :

X1 part number : L77-0358-05

X2 partnumber : L77-0359-05

X101 partnumber : L77-0363-05

Has anyone any idee what types they are HC6 -HC25 or something else ?

And what are the specifications of those crystals ??

The frequency values,I do have found them in the user manual but nothing more.

I need those specifications to let make some new types on demand

Give up,the exact frequency alone is not enough.

I look forward if someone could give me more information.

A Kenwood Email support or information for asking those questions is also helpful.

Kindly regards Jean ON4AEF.

Jean,

You can call International Crystals in Oklahoma City, OK at
*1-800-725-1426. More than likely they will have the crystal information
for the Kenwood TS-700.

The crystals in question with be one of the following holder types

1. HC-26/U stiff pin plug in
2. HC-18/U thin wire solder leads

From looking at the HET UNIT board X50-1170-61 Xray view in the TS-700
service manual, I suspect the holder type is #2. International Crystals
should have that information. I have an old Regency 5 channel FM monitor
receiver that used the same HC-18/U solder lead crystals. When I
ordered the crystals all I had to have was the actual receive crystal
frequency, International Crystals did the rest. My last crystal order
from International Crystals, I paid $22 per crystal plus a few dollars
shipping. I have never found "new" crystals "cheaper". I've found
cheaper "used" crystals but I wanted new with a warranty. I've never
received a bad crystal from International Crystals.

Hi Lou,

Just as a followup, I have removed the 27mhz successfully from the TS520s, I feel much better selling it to the new owner with this removed, I wasnt aware it was in there for all these years then I just happened to be doing a check on all bands before sending to its new owner and heard noise on the aux position. Easy removal and all du eto your help. Your explanation probably keeps Mark Tell from ACMA a very happy man and to be honest, I feel we have done the right thing as far as Ham radio ethics and complying with the law here in Australia as best as possible.
Once again, thanks for all your help, it is so much appreciated.
cheers
Brenton

George,

Take a look at the TS-530S instruction manual, section 4.5, page 20. This will tell you how to calibrate your digital display properly. You basically zero beat with the 10 mHz WWV using the trimmer capacitor accessible through a hole in the bottom left side of the radio (and marked on a sticker on the bottom of the radio). Use a non-conducting tool to turn the trimmer.

Hi Mark,

I'll try to check in with my 530S next Saturday. Didn't know about the net. I have an issue where my digital read is a tiny bit off. Not sure how to get it corrected. When I want to be on 3.915, the readout will be reading 3. 914.9.

See you soon,George

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st, 2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by me, WB0IQK. There were 23 stations checking in under good band conditions. We had 1 new station, KB8TL.

We had the following number of radios checking in.

3 running TS-520(x)
3 running TS-530(x)
5 running TS-820(x)
6 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-830s + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were 17 stations checking in under good conditions. We had 7 new station checking in, KG5HAT, KJ4UGE, N5JUM, W5EBB, K0GIG, KK4PTC, and KI4RCA.

We had the following number of radios checking in.

6 running TS-520(x)
6 running TS-530(x)
0 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-520s + Drake L-4B amplifier.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940's, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, and Jimmy, WB2KNR . I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 - Oct. 2012 Saturday total 754 check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744

check-ins
Nov. 2014 - Oct 2015 Saturdays total 962 check-ins, Sunday total 669 check-ins

November 2015, Saturday's net total = 66, Sunday's total = 46
December 2015, Saturday's net total = 23, Sunday's total = 17 (Month to date)

Paul,

You can see how the driver and both final tube filaments are wired to the HEATER switch and the source of the AC filament voltage, by studying the high resolution TS-520S schematic I have on my website. Simply click on the following link to download the schematic

http://w5rkl.com/wp-content/uploads/2014/04/TS-520S_LARGE-Schematic_Hi-Res.pdf
http://w5rkl.com/wp-content/uploads/2014/04/TS-520S_LARGE-Schematic_Hi-Res.pdf

This file is the same for the TS-520 and TS-520S. It is not the same for the TS-520SE since the TS-520SE eliminated the HEATER switch.

In relation to minor freq display. .01 discrepancy. There is a section in the user manual and a section in the service manual. Do you have a calibrated freq counter? How have you determined it is off freq?

George:

You can of course adjust the 10mhz reference oscillator TC-1 trimmer cap on the PLL board using a "calibrated" frequency counter and/or zero beating against WWV, but today you have at your disposal literally hundreds of "wwv" like stations on the ham bands. Many people are using modern DSP rigs with very accurate TX output frequency.

Depending on where you live and propagation you can listen to 14.300 or 7.255 or 7.258 or the list goes on and on. Simply pick a strong net and tune VFO for natural voice and then adjust TC-1 until the digital display reads the net frequency.

Most of the Service Manual alignment steps can be completed to a "good enough" accuracy if you dont have the test equipment for "good practice" adjustment. This includes the 10mhz reference clock.

Even if you have the test gear it requires a calibrated standard (Rubidium, TCXO, OCXO etc) to check and adjust test gear internal reference clocks. Few average KW hybrid owners own standards like these or have a means to check and adjust their standards. About best you can do if you are in the service business is to have a GPS disciplined oscillator and a Rubidium standard and perhaps a distribution amp driving frequency counters, signal generators, O-scopes, Spectrum analyzers etc. Very common for all of the 10mhz clocks in this kind of test gear to read slightly different due to former owners applying their "golden tweakers" to the trimmer caps. Again this is beyond what the average Hybrid owner needs.

One warning is that if you adjust TC-1 at 14.300 Maritime Mobile net for instance you may find the digital dial will be off 0.1 at 7.255 Ecars net or vice versa. Even moving the rig around can result in TC-1 capacitance change. When adjusting might have to compromise and have that last digit blinking back and forth between 9 and 0 so that display will be reasonably accurate when you change bands.

Jean,

You can call International Crystals in Oklahoma City, OK at 1-800-725-1426. More than likely they will have the crystal information for the Kenwood TS-700.

The crystals in question with be one of the following holder types

1. HC-26/U stiff pin plug in
2. HC-18/U thin wire solder leads

From looking at the HET UNIT board X50-1170-61 Xray view in the TS-700 service manual, I suspect the holder type is #2. International Crystals should have that information. I have an old Regency 5 channel FM monitor receiver that used the same HC-18/U solder lead crystals. When I ordered the crystals all I had to have was the actual receive crystal frequency, International Crystals did the rest. My last crystal order from International Crystals, I paid $22 per crystal plus a few dollars shipping. I have never found "new" crystals "cheaper". I've found cheaper "used" crystals but I wanted new with a warranty. I've never received a bad crystal from International Crystals.

Hi Kenwood members,

I like to change some crystals behind the HET unit of my TS700 transceiver.

Those are from user manual :

X1 part number : L77-0358-05

X2 partnumber : L77-0359-05

X101 partnumber : L77-0363-05

Has anyone any idee what types they are HC6 –HC25 or something else ?

And what are the specifications of those crystals ??

The frequency values,I do have found them in the user manual but nothing more.

I need those specifications to let make some new types on demand

Give up,the exact frequency alone is not enough.

I look forward if someone could give me more information.

A Kenwood Email support or information for asking those questions is also helpful.

Kindly regards Jean ON4AEF.

Mike,

Those are the specifications of the crystals used in a old Yaesu FT707 transceiver.

But not sure if those crystals in the Kenwood TS700 have the same specs ?

Frequency : 00,000 Mhz

Type : HC25/u

Load capacitance : 30 pF

Series resistance : 25 ohm or less

Static capacitance : 7pF or less

Drive level : 5 mW

Calibration tolerance : 0.001

Temperature tolerance : 0.003 from -30°C to +60°C

We have a very good company hier into Belgium for crystal supply on demand : www.ecoxtal.be

But they always need the full specifications for production of a typical crystal..

From there my question around,the working frequency and type of the crystal alone is not enough .

73’s Jean ON4AEF

Hi Jean,

I apologize I didn't notice your ON4 call. I should have noticed you were in Belgium. International Crystals should still be able to help you.

Jean,

You can call International Crystals in Oklahoma City, OK at 1-800-725-1426. More than likely they will have the crystal information for the Kenwood TS-700.

The crystals in question with be one of the following holder types

1. HC-26/U stiff pin plug in
2. HC-18/U thin wire solder leads

From looking at the HET UNIT board X50-1170-61 Xray view in the TS-700 service manual, I suspect the holder type is #2. International Crystals should have that information. I have an old Regency 5 channel FM monitor receiver that used the same HC-18/U solder lead crystals. When I ordered the crystals all I had to have was the actual receive crystal frequency, International Crystals did the rest. My last crystal order from International Crystals, I paid $22 per crystal plus a few dollars shipping. I have never found "new" crystals "cheaper". I've found cheaper "used" crystals but I wanted new with a warranty. I've never received a bad crystal from International Crystals.

Hi Kenwood members,

I like to change some crystals behind the HET unit of my TS700 transceiver.

Those are from user manual :

X1 part number : L77-0358-05

X2 partnumber : L77-0359-05

X101 partnumber : L77-0363-05

Has anyone any idee what types they are HC6 â€“HC25 or something else ?

And what are the specifications of those crystals ??

The frequency values,I do have found them in the user manual but nothing more.

I need those specifications to let make some new types on demand

Give up,the exact frequency alone is not enough.

I look forward if someone could give me more information.

A Kenwood Email support or information for asking those questions is also helpful.

Kindly regards Jean ON4AEF.

Jean,

I can't speak about your local source for crystals in Belgium. I'm sure they provide excellent crystals.

I can, however, speaker about International Crystals in Oklahoma City, Oklahoma. I've purchased numerous crystals over the years from International Crystals and the only information I had to provide was:

1. Make and Model of the radio the crystal is used in
2. The circuit the crystal is used in such as TX, RX, HET OSC,, etc.
3. The frequency of the crystals

International Crystals, in most cases, already has all the capacitance, resistance, and holder type information on file.

I needed a 29.0Mhz TX crystal and a 28.545Mhz RX crystal for my 1960 E.F. Johnson Messenger 202 transceiver I was moving to 10 meter AM. They had all the information needed so all I had to provide was the 3 bits of information shown in the above list. Each crystals cost $22 and took about a week before I had them in my hands.

Can anyone tell me what the VFO, VCO, and CAR levels should be? My readings are 3Vp-p VCO, 1Vp-p for the CAR, and .5Vp-p for the VFO (all measured with a scope). I am taking these readings off the PLL board.

Topic: 53574 Message: 53575

Why are you measuring at the PLL board?

Typically would measure at source when you dont have levels where the radio likes to use them. Service manual is a must.
The Service Manual steps list the levels in RMS +/- dB range. Multiply by 2.828 for P-P levels.

Step 5 states VFO level should be 200mv rms +/- 1dB or 178mv to 224mv.

Step 7 states VCO level should be 1.0v rms +3dB and -2dB or 794mv to 1.4v . This is measured at TP-3 on the RF board where the VCO serves as the LO for the Rx and TX mixers. With experience you will learn that VCO level is bandswitch dependent and VFO position dependent. Measure at 250 and should be approx 1.0v rms. May range from around 800mv to 1.5v or more. Best to measure at TP-3 on RF board because very common to have bad soldering on the mini black coax cable plug and/or at its sockets at PLL board and RF board end. Both center pin and shield can be open or intermittent.

Step 3 states that Carrier Level should be 300mv rms +/- 1dB or 267mv to 377mv.

None of the levels are super critical. I would mark up all the Service Manual steps for the +/-dB tolerances.

Hello Luther!

If you remember me, I was the fellow that repaired a Drake TR4 a few years ago for you. How are you?

A really simple problem that occurs is that the RF gain knob gets turned down by accident. That will shoot the meter up in scale. Check to make sure the rf gain is all the way up.

I have done that myself. I trouble shot the radio for half a day before I realized the problem was me.

Jerry,
Using headphones, how does it sound with MONOITOR switched on when transmitting?

What antenna are you feeding?
RF feedback can cause very rough audio. Poor mic grounding makes it worse.

Is the VFO frequency stable? If not, could be VFO variable cap wiper. Deoxit can fix that.

53583. basic info

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-12-11 22:26:11 UTC
From: Joseph Stiles
Topic: 53583 Message: 53583

Greetings group,
   Over the past months, I've been keeping track of problems that members have asked/reported. I have not compiled spread sheet(s), but have just saved various complaints into similar files. The results(not scientific), point to one basic problem: not reading/referring to the owner/operators manual.
No disrespect is intended to any member, but many problems/difficulties, can be solved by reading/referring to your operator/owner manual(s) FIRST. I have been guilty of violation of that 1st rule. You must ask yourself: If the rig was working fine last night...now it's not, what changed? Do electronic/electrical components go bad from one power off to the next power on cycle...you bet! But make sure that all controls are set per owner/operator manual, then go from there. Some anecdotal comments: My rig was working fine last night, I turned it off, and then moved it to dust behind it. This morning, when it went to tune up for the local net, I could not get any output. The result was: member had inadvertently hit the "SG" switch to "off," on the rear panel. Next: My "S" meter goes full scale when I turn it on. It was fine last night. Result: member had inadvertently moved the RF gain control enough to cause full scale deflection while rig was in receive. Returning RF gain control to full CW position(per manual) "fixed" the problem. Another..I'm guilty of this one: frequency on my digital display doesn't change when VFO knob moved. "DH" or "display hold" button/control inadvertently activated. Do I really have to say what the "fix" was????
  So, to save a lot of time and frustration: Check the basic control settings per your rig specific owner/operator manual FIRST. PLEASE, do not get me wrong here, we invite questions, and are always looking for various answers to our rigs problems...but...check the basics FIRST. Also, you can go to the group home page, and under "conversations" query a problem...say...for example: TS-830S no bias reading. You then can read ALL posts/responses regarding that topic....which may be substantial, or go browse the "files" section. Lots of good info there too.
 Recently, there has been some difficulty regarding requests for assistance and, responses to the requests for assistance. If/when you have a problem with your rig, PLEASE be specific as to the problem. Let us know what testing instruments you have, or have access to, and do you know how to use them! For me, I'm still learning the O'scope...but I'm getting better. It is very difficult to give a member instruction(s) on what to check, IF they do not have even basic testing devices, can not read a schematic, or do not know what is being requested for them to test. Am I all knowing of electronic/electrical theory and/or trouble shooting?.....no. That being said, many of the group members have a very long, and significant background in electrical/electronic use/repair/diagnostics, but even they can not do much good if what they are "talking" about gets lost at the other end. It may seem comical to some, but here is an example taken from the "conversation" archives: "My rig won't power on, where should I go from here?"
     So, in short, check the basics first...then if it "still don't work" give us a call. The motto(s) here are: SAFETY FIRST....then... YOU HAVE TO HELP US, HELP YOU!
  and now....back to your regular programming.......

Greetings(again) group,
   Another group house cleaning post.
   Some newer/moderated members may have noticed that their attempted posts have not been showing up in the group main message area. The reason for this is very simple: they are not "signed" in accordance with the group policy.
  Upon acceptance to the group, your were automatically sent an electronic copy of this group's policies. Unfortunately, it appears that many do not take the time to read the above stated policy. There are several ways to append/add a proper signature to all your messages/posts automatically, I will not go into further detail in this message, as it has been "discussed" aud nausium. Take a few minutes to find out how to do it, and make life a bit simpler for all of us.

Thanks for your time...we now return to our regular scheduled programming..... 73

First thing to check is the antenna. Do U keep an SWR meter in line? What kind of antenna ? Best is a coax fed antenna that is adjusted for low SWR on each band u use. If an antenna fault hapens you still can tune up a tube final with a pi network , maybe the settings will be off your usual settings, but you may have high levels of radiation from your feedline getting into the radio and microfone !. Good luck. My radio is Ham Radio...CW is Real Radio 73, John...K8JD

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by me, WB0IQK. There
were 18 stations checking in under good band
conditions. We had 4 new station, N3AR, N8UWQ, KA8ZZJ, and N2CZD.

We had the following number of radios checking in.

2 running TS-520(x)
1 running TS-530(x)
3 running TS-820(x)
6 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
1 running TS-900

I was running my TS-830s + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
14 stations checking in under good
conditions. We had 7 new station checking in, N6OIL, KB7OUU, and WA7DL.

We had the following number of radios checking in.

3 running TS-520(x)
1 running TS-530(x)
3 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-520s + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:

hi am still having the issue with the breaking up audio report. I have addressed all your recommendations and nothing seemed to help. I do not have any problems on 160 80 or 40 m it is 20 m and above. since I have a rubbery feeling band swich I was wondering if this could be the culprit.
thanks for the suggestions Jerry N8UWQ 73's.

Hi Jerry,

You've given us very little to go on and you didn't mention that it
was band specific in your original post.

Does this problem occur if you transmit into a dummy load?

What is your antenna system on 20m and up?

You say the band switch is rubbery? What does that mean and have you
looked inside your radio to investigate?

A number of members have asked you questions but you haven't answered them.

A "Rubbery Band switch" could be caused by a cracked Band switch shaft coupler.*

Check the band switch coupler, look closely for cracks. If you find the coupler is cracked, you can order a replacement from Ken, K4EAA at his website:

www.k4eaa.com

The BS knob should have no dead band or free play or rubbery feel to it at all. Should have very positive detent positions. I would not operate any KW hybrid with a "rubbery" bandswitch. If the shafts slip out of sync you can end up burning up the finals as you will be unable to select the correct band specific tank coil tap and can experience high off resonance plate current without realizing it.

The 820 arrangement is a bit more complicated with a stub shaft, sprocket, and chain assembly driving the BS shaft on the Coil Pack board and then coupled to the S4 tank coil tap switch inside the PA cage.

The coupler can easily be viewed by removing the rigs covers and looking from the bottom side into a rectangular hole cut in the chassis deck adjacent to the Final Board and Marker Board. Depending on what model year 820 you have the coupler can be white nylon, black nylon or red fibre. The fibre ones do not crack at the locking screws like the white nylon ones do.

Changing the coupling is more involved than on the TS530/830 units.

Jerry,

If you have a TS-820S or and 830S, there is a useful write-up on changing out the band switch shaft coupler on the kenwood hybridrestore-dot-com website.

I have done both, and the 820S, as Terry says, is more involvedt but the description provided is helpful. Be sure to mark the shafts as you dis-assemble, as you do not want to couple together the shafts out-of-sync. That leads to additional trouble!

Good luck!

Dave

I hope this isnt a duplicate but I could not see my latest post so here goes again:(

1. Plastic bandswitch coupler replaced in November on 11/02/2104 during radio refurbishment by Terry K9TW.
2. When I picked up the radio Terry indicated the bandswitch didn't feel right, (rubbery was my definition), and would require a good one from another 820.
3.I was not having audio problems on 160/80/40 meters, just 20 meters and possibly higher (afraid to try)??
4. I am able to tune up and set alc into dummy load and on air.
5. Using an all band end fed long wire with LDG autotuner with swr below 1.5-1.0.
6 voice sound good through monitor with headphones on bands 160/80/40/20

I don't know if the bandswitch is the culprit or not.

Sorry for the confusion by lack of info.
I am just out of shoulder replacement surgery and it is not easy typing.

Thanks
Jerry N8UWQ

The plastic bandswitch shaft coupler was replaced with a brass type on November 2, 2014 when I had the radio refurbished by K9TW. When I picked up the radio Terry stated the bandwich didn't feel as is should but should be ok. I am not sure that my audio issue is bandswitch related, on 20 meters and above, this is where I am asking for advice.

Sorry about not providing all the information up front, as I had shoulder surgery and am just now able to type fairly fluently.

Thanks All.

Hi Lou,
I hope I am answering correctly this time. I thought I had responded to all that sent me ideas.
1. I did not know the issue was band specific until I tried other bands.
2. I don't have any issues tuning up ad setting alc level into dummy load.
3. I am using a multiband end fed long wire 120', with an LDG auto tuner, swr is 1.2-1.5 to 1
4. Rubbery bandswitch feel meaning lack of a strong detent on each band and excessive play between bands.

As it just seems to be higher frequecies, could it be RF getting into
the rig or mic? Possibly due to bad SWR or poor earthing of the rig
directly into ground spike/radials - using the house earth is not a
good idea. ....

Just a thought.....

David G4TUP.

OK,

A number of people have advised you on the band switch so I won't say any more about that.

You say voice sounds good on all bands to 20m through the monitor so I don't think you can use the monitor as a trouble shooting aid.

You have a dummy load which is a good start. Can you listen to your 20m transmission on another receiver while transmitting on the dummy load and then on the antenna? You'll just need a short length of wire in the antenna socket of the receiver.

You say you are afraid to test the other bands (15m &10m). You can't really troubleshoot effectively if you don't have all the facts. You have an almost bomb proof matching network in your PA and another tuner between the radio and the antenna. I would do more investigation.

A number of people have advised you about RF in the shack and it's quite possible that this is your problem. RF in the shack is generally the result of common mode currents on your feedline (RF on the outside of the coax) and can be minimised by the use of a choke balun. A simple choke balun is can be made by coiling up your coax to about 6 inches in diameter. Ten turns is what most people use. You may have to experiment with the location of the choke along your feedline but I would start close by the antenna feedpoint.

With your shoulder in bandages this might be beyond your capabilities so you will need a buddy to help you.

Sometimes with RF in the shack you can see the effect by watching other equipment in your shack. I had RF in the shack on 40m and it would cause the needle on my rotator controller to jump around even when it was turned off. Sometimes with RF in the shack running your hand along the outside of the coax changes the situation. Generally you can see this as a changing VSWR.

Good luck

Lou

Jerry:

I pulled up your Service Report and no where in the report does it indicate I gave your TS-820 back to you with a "rubbery" bandswitch knob. That would be very much out of character for me to do that and if I did that it would have been documented in your report along with a description of why I was unable to fix it.

Your original problem was no Transmit. The root cause for that was a severely cracked white nylon coupler that had allowed the two shafts to slip past each other placing the S4 switch out of sync with the Coil Pack Mixer and Drive coils.

It is possible but not common for the allen head set screws in the new K4EAA brass coupler to have backed off, but again not a common problem. One other possibility is that the JIS (phillips like) locking screws on one or both of the white nylon chain drive sprockets has backed out of their hubs. Again not very likely, but possible. Even though these screws are JIS units you can check the tightness with a phillips head screwdriver.

The 4 allen head screws on the brass coupler are 1.5mm. If you are going to check the tightness be very careful as easy to strip the threads.

1. Is this a new antenna or have you always used this random length end fire wire and tuner with your TS820 with no on air reports of audio problems? OR have you made recent changes to it? 2. End feed can be a problem as you are bringing RF into the shack. What are you pushing against (driven ground rod, water pipe, radials)?
3. You might want to try a counterpoise wire for starters on 20 meters. Approx 16.5 feet just dressed around the perimeter of the room baseboard on the floor.
4. Some folks use an artificial ground or "ground tuner" with random end fed antennas. These usually have a means to measure RF current and are adjusted for maximum RF ground current. Easy to homebrew or MFJ makes one.

Part of your problem is that getting off air reports can be confusing if not useless as many who give them have little experience and cannot describe accurately what they are hearing. Audio breaking up is different than RF on the mic line.

Check in to the Midcars Net at 7.258mhz when WX9DX Jimmy is the controller. He has very good audio play back capability and you can hear for yourself what is going on.

Typically dried grease on the ball bearings in the tuning cap can cause that problem. Also the shaft is a planetary drive and it also gets "sticky" inside. There are tiny ball bearings inside the shaft drive. Lose those and you will have difficulty finding replacements.

There are a lot of posts concerning lubrication. I recommend reading them all carefully. Lubricating it the wrong way can cause more problems.

If you find "dead" spots when tuning the VFO through it range (a typical issue with this VFO), I find the usual cause is dirty friction connections on the tension plate on the back bearing of the capacitor. Cleaning it, in most cases, fixes that problem. I have had to solder a wire on the tension "washer" and connect to the capacitor frame in some severe cases (not for the faint of heart to do). There are posts and information in the file section on removing the VFO.

Lots of great info in the posts and file sections.

Tim

VFO/LMOs that are unstable when tuning are found to have accumulated dirt/dust/grease at the variable capacitors flexible "shaft to frame connection". This dirt/dust/grease causes the shaft to frame connection to fail at certain points throughout the VFO/LMO tuning range. When the connection fails due to dirt/dust/grease collection, the VFO can easily fail causing instability in tuning plus erratic display of the frequency on the digital display if the radio has a digital display.

There are websites that show how to solder a wire/braid between the VFO/LMO variable capacitor shaft and frame but I didn't want to do that. Instead, after thoroughly cleaning the variable capacitor flex shaft to frame connections and removing all the old grease from the bearing end of the variable capacitor's shaft, I replaced the bearing grease with DeoXit L260Ap conductive grease. I have a video on my website that discusses how this is done.

http://w5rkl.com/wp-content/uploads/2015/02/Cleaning-Variable-Capacitor-Flexible-Shaft-to-Frame-connection.wmv

When using a tooth pick to remove the old grease, be very careful.

First thanks for all the helpful suggestions. Just out of surgery I have the time but not the wherewithal I would like. Latest results:
As near to antenna feedpoint as possible I coiled my coax 10x in 6" dia. I have another hf rig so I removed the coax and added a short wire into the jack.I tuned up on all bands and listened to the 820 on the other radio into the dummy load in into the endfed wire, after checking for clear frequency. 160,80,40,&20 sounded good on the other radio, however when I tried to tune up on 15 and 10 meters the power dropped from about 75 watts to almost nothing, along with some static like noise, and a mild smell but not smoke. I returned to the lower bands that sounded good as mentioned above and they all operate ok.
Good to mention that my other radio does not have any problems with the same antenna. I should have mentioned that before.

Hi Tim, I still have the TR4cw but I was trying to install a rtty interface and like an idiot got it hung in full keydown and took a second too long to get it shut down, now it won't go into transmit. Could have done something to the relay. I retired from the group but still live here. Be nice to visit, let me know.

I am referring to actual socket. On the TS-520 pin 4 of the remote socket is the ground. I'm assuming there is a ground pin on the TS-530S socket. I am trying to set up a QRP circuit with a 220k ohm pot and 9 volt battery for PSK31.

James,
If I remember correctly the shell of the "DIN" connector is ground. If you look at the REMOTE socket on the rear...you will see a squarish hole, with I think a triangle shape stamped on the rear panel pointing to it...that's the ground....there should also be a solder tab on the inside

The pins are as follows;

1. Record output (100-150mV AF)
2. Relay common terminal (Not grounded)
3. PTT line
4. Normally opened (relay contact approx 1A, DC)
5. Normally closed (relay contact approx. 1A, DC)
6. ALC input
7. No connection

Thanks,

Greetings group,
I dislike having to restate this group's policies over and over again, especially since a group wide post was sent by me on December 11, 2015 regarding this very topic. All newly accepted members to this group were automatically sent and electronic copy of the group policies, and many have not seen fit to read it, but if they have, do not want to abide by the rules. Over the past 7 days I have rejected over 20+ attempted posts, as they were not signed per group policy, or if they were signed, were appended with not permitted statements...ie.: political or religious. This is not intended to be disrespectful towards any group member's beliefs, this is just NOT the forum. I'm sorry if any group member feels they can not abide by the group policies/rules, but upon requesting membership here, and being accepted, you agreed to abide by the group policy/rules. That being said, I will be directing the Group Moderators to reject any/all attempted posts/msgs that are not properly signed. For your convenience:

53628. Re: [TS-520_820_530_830] Kenwood TS-530S Band Switch Problem.

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-12-19 04:17:29 UTC
From: Joseph Stiles
Topic: 53625 Message: 53628

David,
  Welcome to the group.
   First, what testing equipment do you have, or have access to? Second, do you know how to use them, or someone to assist you? Third, do you have the Service Manual? If not, you can download one for free from several group members: w5rkl"dot"com   or n6wk"dot"com
Fourth, what is your level of knowledge?

When the display goes blank, does the rig otherwise receive? It is suggested that you obtain some good contact cleaner/lube...DeOxit D5 is one, and popular among group members. It can be found at electronic stores..and even Radio Shack. Also, get a can or two of "air duster." You can find it at computer stores, office supply stores...and Walmart. It is possible that the contacts on the bandswitch wafers have junk on them, and need a good cleaning, especially if it has sat unused for sometime.

Let's start with the above, and them move on

David,

Sounds like you may have a radio with one of the CB modifications installed. First, look on the rear panel of the radio to see if there has been an extra switch installed. If so, toggle the switch to it's other position and try the bands where you have a blank display. If they come alive, this is your problem. You can easily remove this modification by tracing the two wires back into the radio. You will probably find they go to connector 2, pin 2 on the PLL board. If you want to remove the switch and put the radio back to it original condition, remove the wires and splice the original wires back together. It is best to use heat shrink tubing to cover the splice. It will likely be a Purple/White wire. I have seen many of these radios modified in this manner and I have several toggle switches in my junk box.

Subject: Replacement PCB coil forms for 144 Mhz

Hi members :

Any one who could give me some more details about those coils.

Types,serial numbers,company and so on .

The unit is named RX-NB unit (XX55-1060-00) in the Kenwood service manual.

To be complete the original Kenwood part numbers of the mentioned coils are the next :

T1 L31-0319-05

T11 L31-0320-05 All 144Mhz coils

T12 L31-0324-05

Basic and standard Neosid or Toko coils are not dimension compatible on the front-end board !

I think they are from a earlier generation of Toko or Neosid ?

The mentioned coils are really a bit bigger in dimension as you can see on picture enclosed !

Enclosed a picture about the coils and board it concerns of the Kenwood TS700.

It concerns of the left 2 coils on the picture and the air coil down under on the picture(air coil must be removed)

I Iook forward If you could give me some possible suggestions around this subject ?

Kindly regards Jean ON4AEF.

David,

If Dick (W0NTA) is correct and you have a rig modified for CB, you will want to not only correct the band switching logic as he says, but give the radio a good look over for other CB type mods, particularly any QRO (higher output power) modifications. I had a 530S modified just as Dick describes that also had modifications to the power supply (for QRO) and the speech processor. Corrections were straightforward and afterward I had a fine radio, but you have to check things out carefully.

Hopefully it's just a dirty band switch, but I'd give it a good look to see if there are other obvious mods. Good luck and let us know what you find!

From: Jean Louis Maridet
Topic: 53632 Message: 53632

Hi all,
After change of Q14 on counter unit display and rx came back to life (see topic no display no RX after storage). But there is still a problem :On 1.5 3.5 24.5 Display and RX are OK.On the other bands, the display and RX work but are 500kHz lower than expected.I checked the VFO output : it is OK and between 5,5 and 6 MHz on all bands.On the bands were the RX is offset, the VCO output looks a bit strange with a double peak on top of the sinus signal.
Any suggest is welcome,

Did you check this with a signal generator? The counter output has nothing to do with the real frequency. It always shows the VFO signal and adds a arbitrary offset to it. This offset is set by a matrix of diodes at the counter board. Plugs 4&5 at the counter board have lines for every switchable frequency and the diode arrays (and logical gates) on the board set the offset that is loaded into the counter for each switchable band.

So any problems with this diode matrix shows as difference between real RX frequency and value shown on the counter. I don't suggest this is the case with your rig, but you should look after it. Additionally, the PLL has several oscillators for the different bands that are switched with the same lines as the counter. These are in the upper left corner of the PLL schematic. The controller lines enter via plug 1@pll board. Check the voltage of these lines at this for all possible settings of the band switch. If there are controlling voltages missing at specific settings of the band switch the PLL doesn't work and the counter is dark. Additionally, exactly one)and only one!) of the wires coming into the PLL via plug 1 must be active. I had similar problems with my TS830S (some positions of the band switch had no RX and a dark display), this was easily tracked to shorts between some lines of plug 1. On some settings more than one line was active and the correct oscillator wasn't working... The counter display gets dark when no PLL lock is found.

Martin

Topic: 53625 Message: 53637

David,

OK-first of all, a reminder that looking for and resolving any QRO mods will involve looking into and around the radio's power supplies and this involves working around high DC voltages, from 200 up to 900VDC in the power supplies and around the final amplifier cage. BE CAREFUL when working in these areas and take care not to get yourself across any of these voltages with the risk of death if you make a mistake!

What you're looking for mainly is a re-wiring of the 210A screen voltage supply to the 300B supply on the Rectifier board to increase screen voltages to the 6146B finals. Hints may include obviously changed/re-soldered wiring and jumpers around these circuits, a clipped or bypassed 470 ohm R11 resistor on this board. I also found that the 6.8K R85 on the AF board in the "bias" adjust circuit had been replaced with a lower value (3.3K) resistor.

If you find that these types of mods have been done, you can reverse them to restore the circuits to the original configuration found in the Service Manual circuit diagrams. The key is to spend a good bit of time poking around in the rig looking for ANY mods, now that you've found the one.

The QRO mod gets a few more watts out of the radio (insignificant on the receiving end), but puts stress on the final amplifier. If you see that the power supply has been changed like this, I also suggest looking at: 1) the cathode resistors on the final amplifier board (4 x 20 ohm wired in parallel to ground-- you should see 5 ohms to ground measured from either of the cathodes), 2) Components around the 6146B tubes including the disk caps, particularly the little RF choke at the base of the plate choke to see if any are cracked and/or burned, and the plate choke itself to see if it is discolored or burned, and 3) R37 (3.3K 1W metal film) on the RF board by the driver tube-it can be stressed by the higher voltage as well.

David, if you find these types of mods have been done and you want additional information, I'm happy to help further.

Hello Group, having just acquired a real nice like new TS 530S and reading thru the manual I find a problem that perhaps some one in the group can help me identify and correct a problem. Per the manual when going to transmit one of the first steps is, place meter to ALC, mode to tune position and peak the meter reading using the drive control with the CAR control advanced to establish a drive signal. I get nothing nota no swing on meter. Now if I put the meter into Ip and look at the plate current I can peak the plate current with the car control advanced full and then use the drive to peak the Ip and then dip the plate, then advance load peak the driver again and go, the rig will load up and produce full output. I have even had it on the air and sounds great. Suggestions would be welcomed. Frank KD7HVL

53640. TS530S : display and RX 500kHz down

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-12-19 21:36:09 UTC
From: Jean Louis Maridet
Topic: 53640 Message: 53640

Hi all,
After change of Q14 on counter unit display and rx came back to life (see topic "no display no RX after storage"). But there is still a problem :On 1.5 3.5 24.5 Display and RX are OK.On the other bands, the display and RX work but are 500kHz lower than expected.I checked the VFO output : it is OK and between 5,5 and 6 MHz on all bands.On the bands were the RX is offset, the VCO output looks a bit strange with a double peak on top of the sinus signal.
Any suggest is welcome,
73 de Jean-Louis F5DYD

53641. RE: [TS-520_820_530_830] Re: Kenwood TS-530S Band Switch Problem.

David,

Simple things first: is the SG switch "ON" on the back of the radio?
Filaments lit in the tubes?

Dave

KC3CIP

Thanks Dave,

Right now I am not getting anything out of the RF stage while trying to
tune. Meter doesn't even move when I adjust the drive in Tune.

Thanks
David

[TS-520_820_530_830] wrote:

David,

OK-first of all, a reminder that looking for and resolving any QRO mods will
involve looking into and around the radio's power supplies and this involves
working around high DC voltages, from 200 up to 900VDC in the power supplies
and around the final amplifier cage. BE CAREFUL when working in these areas
and take care not to get yourself across any of these voltages with the risk
of death if you make a mistake!

What you're looking for mainly is a re-wiring of the 210A screen voltage
supply to the 300B supply on the Rectifier board to increase screen voltages
to the 6146B finals. Hints may include obviously changed/re-soldered wiring
and jumpers around these circuits, a clipped or bypassed 470 ohm R11
resistor on this board. I also found that the 6.8K R85 on the AF board in
the "bias" adjust circuit had been replaced with a lower value (3.3K)
resistor.

If you find that these types of mods have been done, you can reverse them to restore the circuits to the original configuration found in the Service Manual circuit diagrams. The key is to spend a good bit of time poking around in the rig looking for ANY mods, now that you've found the one.

The QRO mod gets a few more watts out of the radio (insignificant on the receiving end), but puts stress on the final amplifier. If you see that the power supply has been changed like this, I also suggest looking at: 1) the cathode resistors on the final amplifier board (4 x 20 ohm wired in parallel to ground-- you should see 5 ohms to ground measured from either of the cathodes), 2) Components around the 6146B tubes including the disk caps, particularly the little RF choke at the base of the plate choke to see if any are cracked and/or burned, and the plate choke itself to see if it is discolored or burned, and 3) R37 (3.3K 1W metal film) on the RF board by the driver tube-it can be stressed by the higher voltage as well.

David, if you find these types of mods have been done and you want additional information, I'm happy to help further.

David,

If Dick (W0NTA) is correct and you have a rig modified for CB, you will want to not only correct the band switching logic as he says, but give the radio a good look over for other CB type mods, particularly any QRO (higher output power) modifications. I had a 530S modified just as Dick describes that also had modifications to the power supply (for QRO) and the speech processor. Corrections were straightforward and afterward I had a fine radio, but you have to check things out carefully.

Hopefully it's just a dirty band switch, but I'd give it a good look to see if there are other obvious mods. Good luck and let us know what you find!

David,

Sounds like you may have a radio with one of the CB modifications installed. First, look on the rear panel of the radio to see if there has been an extra switch installed. If so, toggle the switch to it's other position and try the bands where you have a blank display. If they come alive, this is your problem. You can easily remove this modification by tracing the two wires back into the radio. You will probably find they go to connector 2, pin 2 on the PLL board. If you want to remove the switch and put the radio back to it original condition, remove the wires and splice the original wires back together. It is best to use heat shrink tubing to cover the splice. It will likely be a Purple/White wire. I have seen many of these radios modified in this manner and I have several toggle switches in my junk box.

53642. Re: [TS-520_820_530_830] TS 530S ALC drive peaking problem

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-12-19 22:47:54 UTC
From: Joseph Stiles
Topic: 53638 Message: 53642

Frank,
Your problem indicates a very common problem called "no ALC in tune." In "tune" the voltage to the final tubes is significantly reduced so as not to damage them with full voltage(850-900+VDC) while in an out of tune condition. In this case, the problem is most likely resistors 15 & 16 on the rectifier board(x43-1370-02) which is on the underside of the rig. Both top and bottom covers need to be removed to access it. These are both 56k(green-yellow-orange) carbon resistors, and form a voltage divider circuit. You can check the voltage at the "TUN" post on the rectifier board with a meter that can read 200-300VDC. You must be careful here!!!!! If you feel unsure for any reason...ask for assistance from a local helper. You will be poking around a very small area that carries up to 900+VDC, and can, and will make you SK in a hurry if you are not careful. The reading at the "TUN" terminal will be around 200-225VDC. This value is not set in stone. I usually just replace them if I find the "no ALC in tune" problem. If as you say, the rig seems to work fine other than that...good HV, 60mA resting Ip(in USB/LSB) and approx 100watts out with about 225mA Ip at full output (in CW) at key down...this is probably your problem. Good replacements can be had from: hybridrestore"dot"com   ork4eaa"dot"com   you may be able to get locally sourced parts...or from Mouser or Digikey. Stay with the same wattage...1/2W...I usually use metal film replacements.

Jean,

You need to pull the counter board out and check under high magnification and high lighting, all the foils and pads for cracked and dry joints. Check for line continuity for all plugs going into board.

Dave,

The Kenwood MC-50, Shure 444, or a Astatic D-104 are examples of microphones that will work with the TS-520 series transceivers. The TS-520 series transceivers' microphone impedance is 50K ohms.

Jean: On page 51 there is a connection identified as .5 Mhz shift on counter board, might be this. It's the little connector.

Please refer to Pages 5 and 6 of the service manual.
It could be that part of the BCDA signal is interrupted. Particularly the digit that shifts 500.
You would notice that 1/5, 3/5 24.5, 28.5 and 29.5 bands would count correctly the others would be off 500.
It's probably just a bad joint or connection.
You should be able to trace this on the counter board.It could be the BCDA in or out on the counter board.
The A part of the BCDA probably does not change according to the chart on page 5. The BCDA in/out is on page 6.
Should not be too hard, might be just a dirty or bad solder connection or bad trace.

Hi Dave,
Yes it requires a 4-pin plug. If you could find a Kenwood MC-50 with 4-pin plug that would be ideal. Otherwise when I still had my TS-520 I used a Shure 444 mic and got excellent audio reports. I checked on eBay and both mics are available but be sure it comes with a 4-pin plug, as I noticed some are being offered with a phono plug.

Hope that helps.

73s and Happy Christmas!

Dave: I have used may different mics with the hybrids. Any mic with over 600 ohm impedance seems to work just fine. As far as the four pin connector goes, there is a wiring diagram in the operator manual.
D 104 mics work fine but are omni directional and pick up anything in the room. Some people do not think the sound they produce is very good. It cannotbe too terrible since they made and sold so many.
I like my EV dynamic mic. Even a cheap Karaoke mic will work, but then you need to cobble together a PPTswitch.
When wiring, keep the GRNDS separate as in the wiring diagram.

The SG switch performs 2 functions:

1. The "ON" position provides a path for the Rectifier Unit's 210A supply to provide positive DC voltage to the 6146 screens, pin 3 on the final tube sockets. This is the normal position for the SG switch.

2. The "OFF" position provides a path for the Rectifier Unit's -C bias supply to provide negative DC voltage to the 6146 screens, pin 3 on the final tube sockets. This position is used when neutralizing the final amplifier but only AFTER the transmitter has been tuned to maximum RF output with the SG switch set to ON (see the operator and/or service manuals for the steps in neutralizing the final amplifier).

There will be no IP (cathode to screen and plate) current flowing in the final tubes if the SG switch is set to OFF. However, there will be cathode to grid current flowing with the SG switch set to OFF because the SG switch has no control over grid current flowing in the tubes, only current flowing between the 6146 cathode and screens/plates. You can see this by setting the SG switch on your KW hybrid to OFF then perform the normal TUNE mode ALC peak adjustment. You will notice you can achieve a strong peak ALC Indication but switching the meter switch to IP, the meter drops back to zero, indicating no cathode to screen/plate current is flowing in the 6146 final tubes.

Frank,
A quick look at the TS-530S Operators/owners manual on Pg 26, Section 6.5 would have answered your question. Severing this line between Connector #6 Pin 1 (TOF) on the RF board, and Connector #7 Pin 4 on the AF board, enable the WARC bands.
If you do not have a manual, you can download one at: w5rkl"dot"com or n6wk"dot"com (free from both sites)

Frank,

That's the WARC band disable connection. This wire is cut to enable the
WARC bands.

"TOF" refers to "TX Stop signal for WARC" as stated in the TS-530
Service Manual, page 51, item 7 under AF Unit.

Date: 2015-12-20 19:42:12 UTC
From: Mark Gilger
Topic: 53665 Message: 53665

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by me, WB0IQK. There
were 14 stations checking in under good band
conditions. We had 4 new station, N1PGQ, and VO2GD.

We had the following number of radios checking in.

2 running TS-520(x)
3 running TS-530(x)
2 running TS-820(x)
4 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-830s + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
21 stations checking in under good
conditions. We had 6 new check-ins, KC3O,
KF5FHZ, KD0ZCP, KG0PP, KD0SUY, and KK6PVS.

We had the following number of radios checking in.

7 running TS-520(x)
2 running TS-530(x)
4 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
1 running 599 twins
0 running TS-900

I was running my TS-520s + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and

TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 □ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins
Nov. 2014 □ Oct 2015 Saturdays total 962 check-ins, Sunday total 669 check-ins

November 2015, Saturday□s net total = 66, Sunday□s total = 46
December 2015, Saturday□s net total = 55, Sunday□s total = 52 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo

Mark, WB0IQK

53666. RE: [TS-520_820_530_830] Re: Kenwood TS-530S Band Switch Problem.

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-12-20 19:57:37 UTC
From: David Boothe
Topic: 53625 Message: 53666

David,

OK. I assume that you are following the tuning procedures in the Instruction Manual and that you are seeing nothing on all bands.

SAFETY FIRST: Much of what's below involves getting inside the radio and working with or in proximity to high voltages, up to 900V. Take great care when running these checks, in particular discharge the HV capacitors after the radio has been on and then switched off with the power cord disconnected. Do this by waiting a few minutes and then by touching an insulated screwdriver with a clip lead attached to the chassis ground to the top of the plate choke inside the final cage. For safety, leave a clip lead attached between this point and the ground to avoid a shock from any "bounce back" of the HV caps.

First, I'd check the band switch coupling inside (you can see it through a cut out in the final case with the covers off) to see if it is loose (or broken). The white plastic couplings often crack at the set screws, become loose or just break in two and the switch will not rotate properly inside the final cage. Movement should be crisp into the detents. If the coupler is broken, you can replace it with brass couplers available on line and guided by tutorials at the websites where you can obtain the coupler. Clean all the band switch contacts/wafers with DeOxit 5 or equivalent. Dab it on to the wipers with a small artist brush and rotate repeatedly. Recommend you do this cleaning no matter what.

Next, a couple of things to check with the transmitter into a dummy load:

1. If you switch the Mode switch to USB or LSB and the meter switch to HV, are you seeing any high voltage reading on the panel meter HV scale when you key the transmitter? Should be about 900V.
2. With the Mode switch still in USB or LSB, and the meter switch in IP, are you seeing around 60 ma idle plate current when you key the transmitter? If not, try to adjust it per the Instruction Manual using the BIAS control on the back.

If these are OK, you may want to try new tubes if you have known good spares on hand, particularly the 12BY7A driver tube. Be sure to replace the tube shield on the driver tube and tuck the metal spring strip mounted to the tube socket inside between the shield and the tube. If you don't have spares at this time or if new tubes don't change anything, I'd go ahead with the voltage checks below.

If either 1 or 2 above not OK, you probably have issues within. You can search this group for "no output" and "no ALC in tune mode" and get many

good notes for what to check. If it were me and I didn't see one or both of the above, I'd open her up and check:

1. Power supply voltages-If you see no panel HV reading from the above check, you may have bad HV electrolytic capacitors. Check for HV again at the top of the plate choke in the final cage, where the 6146B plate caps attach. You must have a meter and leads capable of measuring at least 1000VDC to do this. Look for around 850-900VDC. Again, BE VERY CAREFUL you when check this and other voltages in the rig that can be lethal if you get across them. In RECEIVE mode, on the Rectifier Unit, check the 300B (around 360VDC), 210A (around 255-265VDC), and -C (around -110V) voltages. Look for any mods that I described in my prior note while you do this. If these are OK and no mods, go on.
2. TUBE VOLTAGES-check the DC pin voltages for the 12BY7A driver and the 6146B finals against the values in the main schematic in the Service Manual and note them, first in RECEIVE and then in SEND. You should see something close to the values specified and THEY SHOULD CHANGE AS INDICATED when you switch from RECEIVE to TRANSMIT.

If any of these voltages are not present or wrong, you'll need to run down the cause and correct it. Some things to check depending on what you see:

1. NO HV at 6146B plate -HV circuit on Rectifier Unit and/or HV electrolytic filter capacitors mounted on the chassis in in front of the power transformer.
2. HV AT 6146B PLATES, BUT NOT ON PANEL METER (HV SETTING) IN SEND MODE-Check the HV divider resistors on the Rectifier Unit (R15& R16, 56K). These often fail high. IF OK, problem may be a problem with the multi-function relay, RL-1. RL-1 is located on the IF board on top of the radio-large square relay. If this turns out to be the problem, it will probably need to be replaced. Listen for it cycling when you switch from RECEIVE to SEND. Even it it cycles, the contacts may be bad, especially on old radios that have been sitting for a while. Contact cleaning is difficult on this unit. Replacements are available on line.

If all this checks out OK, you'll have to go back to the drawing board and/or consider trying new tubes.

David, I hope this helps as a starter. Your prior note indicates you have the equipment and knowledge for these checks. Let us know what you find and certainly other members of the group can add to this or correct if I've gotten something wrong. Mainly you have to look, check, and compare against the diagrams and the manual and think your way through the problem.

Dave

On 12/19/2015 12:37 PM, 'David Boothe' <mailto:boothedw@...>
boothedw@... [TS-520_820_530_830] wrote:

David,

OK-first of all, a reminder that looking for and resolving any QRO mods will
involve looking into and around the radio's power supplies and this involves
working around high DC voltages, from 200 up to 900VDC in the power supplies
and around the final amplifier cage. BE CAREFUL when working in these areas
and take care not to get yourself across any of these voltages with the risk
of death if you make a mistake!

What you're looking for mainly is a re-wiring of the 210A screen voltage
supply to the 300B supply on the Rectifier board to increase screen voltages
to the 6146B finals. Hints may include obviously changed/re-soldered wiring
and jumpers around these circuits, a clipped or bypassed 470 ohm R11
resistor on this board. I also found that the 6.8K R85 on the AF board in
the "bias" adjust circuit had been replaced with a lower value (3.3K)

resistor.

If you find that these types of mods have been done, you can reverse them to restore the circuits to the original configuration found in the Service Manual circuit diagrams. The key is to spend a good bit of time poking around in the rig looking for ANY mods, now that you've found the one.

The QRO mod gets a few more watts out of the radio (insignificant on the receiving end), but puts stress on the final amplifier. If you see that the power supply has been changed like this, I also suggest looking at: 1) the cathode resistors on the final amplifier board (4 x 20 ohm wired in parallel to ground-- you should see 5 ohms to ground measured from either of the cathodes), 2) Components around the 6146B tubes including the disk caps, particularly the little RF choke at the base of the plate choke to see if any are cracked and/or burned, and the plate choke itself to see if it is discolored or burned, and 3) R37 (3.3K 1W metal film) on the RF board by the driver tube-it can be stressed by the higher voltage as well.

David, if you find these types of mods have been done and you want additional information, I'm happy to help further.

David,

If Dick (W0NTA) is correct and you have a rig modified for CB, you will want to not only correct the band switching logic as he says, but give the radio a good look over for other CB type mods, particularly any QRO (higher output power) modifications. I had a 530S modified just as Dick describes that also had modifications to the power supply (for QRO) and the speech processor. Corrections were straightforward and afterward I had a fine radio, but you have to check things out carefully.

Hopefully it's just a dirty band switch, but I'd give it a good look to see if there are other obvious mods. Good luck and let us know what you find!

David,

Sounds like you may have a radio with one of the CB modifications installed. First, look on the rear panel of the radio to see if there has been an extra switch installed. If so, toggle the switch to it's other position and try the bands where you have a blank display. If they come alive, this is your problem. You can easily remove this modification by tracing the two wires back into the radio. You will probably find they go to connector 2, pin 2 on the PLL board. If you want to remove the switch and put the radio back to it original condition, remove the wires and splice the original wires back together. It is best to use heat shrink tubing to cover the splice. It will likely be a Purple/White wire. I have seen many of these radios modified in this manner and I have several toggle switches in my junk box.

53672. TS-830S Electrolytic Cap Replacement

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-12-21 03:54:59 UTC

How difficult is it to replace the bias caps in a TS-830S transceiver? (I am not familiar with TS-830S and own one. I've refurbished a lot of boat anchors but have never owned or worked on a Kenwood hybrid rig of this type.) I don't even know if they are in the power supply or radio itself. Same goes for any other Japanese radio. I've worked on Kenwood, National, Swan, and Collins all of American design, but never Japanese radios. They kind of scare me.

One last thing. How difficult is it to replace all the electrolytics in the radio? I mean ALL of them, even the small low voltage ones. I have never even opened mine up to look inside it. That shows you how much I know about Kenwood. Ask me about Drake and I know a lot, but not on Kenwood.

Good day,

Why would you want to change all the electrolytic caps? Have you identified a particular problem? Unnecessary heating and moving molex connectors usually end up causing more problems than anything. The old phenoic boards are very susceptible to heating. The HV caps should be replaced as they are renown for failure and highly recommended to be changed, including on IF board.
The RL1 relay on AF board is a source of problems and it is recommended to be replaced. However,this is your radio and only you can decide on the mammoth job of cap replacement. There are a number of suppliers of cap kits. I personally use 105 degree caps when a problem is detected.

From: bsa0791@...
Topic: 53675 Message: 53675

My TS 520 jumps back and forth slightly in frequency. I have been told this is certainly the back of the capacitor needing to be cleaned. I have attempted cleaning the capacitor at the rear by spraying the back of the shaft with dexoit and working it back and forth many times. No help.

I was told the problem is that the cleaner is not migrating between the contact on the shaft and frame of the capacitor.

Im ready to try it again. would you suggest total removal of the vfo unit and attacking it that way. The many other times I tried, the 520 was on its side and I accessed the rear contact through the door.

Brian,
Does the freq. shift around while the vfo is just
sitting or when your tuning does it jump around
erratically at certain points in the 500khz tuning range?

The problem with the tuning cap cleaning
typically will fix the erratic tuning problem. I
don't think it will help if your vfo is jumping
around while it's just sitting there on the table.

One thing you might try is using DeOxit on (I'm
assuming your using DeOxit D5, right?) the RCA
plug (VFO Output) and power plug pins on the rear
of the vfo assembly. I' m currently playing
around with some Heathkit SB-101's and 102's and
that is a know problem with the VFO output RCA
plug on the rear of their vfo's. Out of the 4
SB's I'm working on, 3 have that problem.

You might also want to check the VFO power to
make sure it's stable. If it's jumping around,
that might be causing your problem.
VF9 I think is the adjustment for that and it's
on the Fix. Ch AVR board. It might need to be cleaned.

Mark

Lee:

None of us have answered your initial question regards "bias caps". I assume you mean C5 and C6 -C supply filter caps.

If so, it is relatively easy to change them.

After having radio unplugged and discharge the HV and 300/210 filter caps you remove the 4 Rectifier Unit board hold down screws and carefully roll the board over and unsolder C5 and C6.

While there I would measure R11 470 ohm pi filter resistor and R9 330k bleeder. Very common for R9 to be very high or even go infinite which means that the 300 supply caps on the IF board can retain a charge for a very long time and give you a nasty surprise.

I am curious what operational problem you are seeing with the -C supply that leads you to believe the C5 and C6 need changed. Have you measured the ripple on it?

In my experience they seldom fail. You can view the rupture vents with a dental mirror and they are among the very few aluminum electrolytics that you can ESR in place. I would say a maximum acceptable ESR of around 0.60 ohms.

Nicole,
The metal strip is attached to the driver tube socket, not the shield. I have had the same thing happen. If the metal shield just won't come off, try taking some needle-nosed pliers and GENTLY spread open the top of the shield while exerting a slight pull to get it off. Once you get it off, you can squeeze it back into shape(it's spring steel)...this time possibly...with a slightly looser fit. After you get the driver out, inspect the solder joints of the tube socket on the foil side of the RF board. Those joints are 30+ years old, and several may have cracked in your attempts to remove the driver. As far as testing your final amplifier tubes...that's OK to indicate a short/totally fried tube, but it will NOT indicate that the tube will operate in the actual RF environment. Best way to test your final amplifier tubes are in the rig.

Steve,
The tinted lens is held in/on by glue. You can remove the digital display and get to it that way, or remove all the knobs, etc., and remove the whole front panel. Now you can give all the knobs etc, a good cleaning, and fix the window. You'll need a 5/64th" "allen" type wrench for loosening the screw on the band switch, and a 3mm for the VFO screws. You do not have to remove the VFO knob. The VFO unit will come out as a unit...just be careful of the lamps..which can be removed by sliding the soft lamp holder forward, and the connection at the rear needs to be removed also.All the rest of the knobs should pull right off...be very careful however of the pointer on the plate control.

You can remove the complete counter board by removing four screws (two on top of the frame, holding a yellow/gold tin bracket surrounding the display and two with white plastic holders toward the transformer). Leave all wires and plugs in place. Be a little careful, the gas discharge display is made from glass and no longer available new.

The wires are long enough to allow moving the complete counter module out of the way and access the inside of the display window.

Thanks Dave,

Looks like I will have a lot of homework to do now. With all that is going on I may not get to it right a way. I appreciate all of your assistance. My back ground is electronics. I grew up in the 60's fixing tube radios and TV's. I get the safety message and always appreciate the reminders.

I will get you posted on my progress.

Thanks again.
David

Thanks Mike,

I get nothing on the ALC with the SG switch on or off.

Thanks for the info Terry. My experience with other radios has been high voltage bias filter caps go bad and then cause the finals to get wiped out. I picked this radio up and the B+ high voltage caps were replaced by the previous owner but not the bias caps. I'll replace R-9 and R-11 while I am at it. Thanks for the tip.

I realize this is a hazard, but electrolytics back then were never designed for a 40 year life. As I said, I am not familiar with Kenwood hybrid rigs. I am sure the quality of the Kenwood caps would determine later failure rates to some degree. So what has the failure rate been with you guys having used these rigs extensively?

I understand, Dave. The idea does scare me. However, if the caps are going bad these days the process should be done. Electrolytic caps back then were never designed to live 40 plus years. Maybe it comes down to it is risky leaving them in as well as replacing them causing another type problem.

Mark,
Yes, it only jumps sitting still. I mainly use the 520 on cw. The operator on the other end can hear it moving when I transmit and I can hear it on rx. Sometimes it does not do it much, very sporadic and leaving it on an extended period of time does not help.
One thing I forgot to add, the problem is corrected with an external vfo. So it is isolated to the units vfo unit and not the supporting circuits.
What do you think?
Brian KB4MNG

Topic: 53665 Message: 53691

The HV caps were most likely replaced by former owner as owners have been advised for quite some time now to replace them. The top one in the pair is the one that does fail from time to time and when it does you will read 450vdc on the panel meter in lieu of 900vdc. Probably 90% of all the caps in the Final 900vdc B+ supply in all the KW Hybrid models are in service with swollen and/or cracked rupture vents and ESR slightly high.

That does not directly correlate to the -C filter caps.

I can count the number of TS830 thermal runaway events that I have had to troubleshoot and repair on the fingers of one hand. Common root cause is dirty or bad bias voltage adjustment pot or bad Molex Conn 8 on the Audio Board. On the TS820s it is bad molex connectors on the RF board as the bias pot is a bit more robust.

I would suggest that you should consider replacing the 300 and 210 supply caps on the IF board. You cannot view the rupture vents. These caps very seldom fail, but I replace them when pulling the IF board for RL-1 relay replacement. The reason I replace them is they dont have much WVDC head room (350vdc). I install 22uf 450vdc Nichicon units as the Driver tube anode voltage typically runs 345vdc or higher.

Of course your radio and you can do whatever you want. Just trying to help you make an informed decision.

I just sent Hybrid unit number 58 for the year out the door so my opinions are based on a bit more than tribal lore or what I believe. By the way only two thermal runaway events in that population and none due to bad -C supply filter caps.

It is pretty clear you have made up your mind. I hope you have a good professional de-soldering tool. I would like a report back on how many lifted pads,foils,jumper wires or long capacitor lead wires folded over to bridge the induced defects that your radio ends up with that were not there when you started. If you are good and a bit lucky it can be done without damage to the boards. I have seen some real abortions most notably on the IF boards that are pulled numerous times. Some people should not be allowed to use a soldering iron!

Take your time and have fun.

Terry K9TW

Seems like there was a ham a year or so back that did a shotgun replacement of all the electrolytic caps in a hybrid. It worked prior to the replacement, did not work after.

Well I don't think it's a power problem, since
the remote VFO get's it's power from the
radio. Try cleaning the connectors mentioned in
the last post with some Deoxit and see if it gets any better.

Replacing ALL other electrolytic capacitors simply because they are old is not a good idea. The capacitors I would replaced due to age would be the 2 HV filter capacitor, C22 and C24, both 100ufd 500VDC along with all 4 of the LV filter caps on the IF Unit, C178, C179, C180, and C181 LV filter capacitors.

The remaining electrolytic capacitors, unless there is evidence of failure during troubleshooting, I would leave alone/note replace.

Yes, it's true if the Rectifier Unit's "-C bias supply" fails the final tubes will conduct to the saturation level. However, the failure rate of the two Rectifier Unit's "-C bias supply filter capacitor's, C5 and C6 both 33ufd 160VDC, is very low.

The issue with replacing ALL electrolytic capacitors, same as replacing ALL resistors, due to age is the PC board foil runs, component lead pads and board edge pin pads have a tendency to crack/break when heated creating one or more NEW problems the radio did not initially have. PC board foil runs/pad cracks/breaks are not readily evident. More often then not they are very difficult to see. The solder connection may "appear" okay but there could easily be a crack/break at the junction of the foil run and pin/component pad. An example is when I replaced a defective relay on the IF Unit board in a TS-120. I thought everything was good after checking my work until I powered up the 120 and noticed the "S" meter didn't work. The meter is routed through one of the SPDT relay terminals. A very small, very difficult to see, crack/break occurred at the junction of the relay pin pad and the foil run. The body of the relay overlapped the pin so I could not use a high intensity flash light and a magnifying glass to see the crack/break. The only way I found the crack/break was to use an ohm meter to check continuity between the relay pin and the foil run. Now consider the possibility of one or more foil run/pad cracks/breaks that could easily occur after replacing all those smaller electrolytic capacitors then powering up the radio and a "NEW" problem now exist. What is causing this problem? Bad solder connection on the board or a crack/break in a foil run/pad? Which one? I have seen similar failures occur in Heathkit PC board foil runs and wire/component lead pads. I've seen when a component pad is heated just enough to soften the solder to remove a failed component, the entire pad lifts off the board and breaks off from the foil run.

It's up to you whether you want to replace ALL the electrolytic capacitors and risk creating PC board foil run/pad problems the radio didn't inititally have or replace only the HV and LV filter caps as stated above.

I have a video on my website that shows how to clean the VFO's variable capacitor shaft to frame connection.

http://w5rkl.com/wp-content/uploads/2015/02/Cleaning-Variable-Capacitor-Flexible-Shaft-to-Frame-connection.wmv http://w5rkl.com/wp-content/uploads/2015/02/Cleaning-Variable-Capacitor-Flexible-Shaft-to-Frame-connection.wmv

I am also working on a couple of new videos that will cover cleaning the TS-520/TS-820 VFO variable capacitor shaft to frame connection on both ends of the capacitor shaft. A video will show how to safely remove old dried out bearing grease and apply new grease.

I have other VFO videos I plan on making that cover how to measure the VFO's output frequency range using a frequency counter and view the VFO's output RF sine wave using a simple scope.

From: kk6fut@...
Topic: 53665 Message: 53697

Hi all, I'm a lurker but proud owner of a TS-820S and a TS-520 and thought I'd ask W0VT's question about failure rate. I'm a relatively new ham but (before the random flaming starts) consider myself fairly competent with the soldering iron, oscilloscope, and all the other tools of the trade, etc. (I also do a lot of homebrewing...)

Anyway, I ended up replacing most of the caps in my TS-820S, but did not do a wholesale "heck I'll recap the whole thing just because people say so".

My TS-820S was humming along nicely until a year or so ago, when, gradually, my SSB audio level started dropping (and corresponding RF, voice only). Full output on CW, but SSB ended up at no audio, eventually. An inspection of the IF board found a number of visibly leaking caps; I replaced only the caps in the audio path, which MOSTLY fixed the issue (see below) -- apparently I was losing signal through one of the degarding caps replaced to the mic amp. Notably, not all of the caps which were replaced were visibly leaking-- I ended up having to replace a number of them within the path which looked perfectly fine, but were bad (oscilloscope confirmed -- no signal as expected on one side of the cap).

After running for a little longer, suddenly, the sidetone on CW started to go crazy... Tone shifted randomly everywhere for about a week, and then it went out completely. Cracking open the case, found the appropriate capacitor related to the CW sidetone frequency, and fixed that.

Then, my VOX stopped working -- replaced all the capacitors on the FIX-VOX unit, which fixed that problem.

Finally, and most recently, I started having strange issues with PLL unlock -- bands would be in then out, and then completely no PLL lock on any band. I ended up re-caping the entire PLL, VFO sections (and a few other boards while I was in there), and the HV caps since I figured all my capacitors were going. After the more-or-less wholesale change out of all the rest of the capacitors in the radio, everything is working great and checks out per the alignment procedures etc... And (see above)--suddenly my SSB audio output REALLY started working well -- apparently my earlier fix only partially fixed my signal loss (probably just the mic amp stuff, and not other losses in the system from degrading capacitors).

So yes, your capacitors might hit their lifetime while you are using your rig! I would advise changing out one board at a time if you do decide to re-cap, and testing those boards STEP by STEP (ie, fix audio first, check for cold solder joints and continuity, etc etc, then move on to the next board, etc.) -- and if you don't know how to test a radio board by board, don't do it yourself--definitely don't wholesale change everything without testing each unit individually after your replacement.

(btw, the other fixes I have had to do was initial cleaning of the band switches and all the pots when I purchased the radio--removed about 2 inches of accumulted dust, too--plus fixing intermittent pins in the frequency display, and replacing the HV unit resistors, which were WAY out of spec when checked, and a bit toasty---symptom was no ALC output on TUNE on 15m and 10m, and strange behavior on TUNE - I've had to do that same fix on my

TS-520, after a damp Field Day where I suddenly lost TUNE ability).

Trying to chase this problem down. On the rectifier board 43-1370-02 I removed and replaced the 2 56K resistors. They did not look bad but I replaced them anyways, the Screen grid voltage is right at 245 VDC under CW and SSB and tehn going to tune goes to 130 VDC. This does seem a little low.
Looking at the schematic I find R15 but no R16. This is the resistor that would go to ground forming a voltage divider from the 245 VDC rail, and with this resistor to ground I would expect to see right around 130 VDC from the 245 VDC rail. I can see on the circuit board where the resistor should go, but again on the schematic I down loaded, I find no R16. considering I also so see a few other components that have labels or nomenclature but no component trying to figure out what is going on. Again the board did have a R16 installed.

Frank,
The absence of R16 on the Rectifier Unit section of the TS-530 schematic is an error. R16 is on the Rectifier Unit but NOT on the schematic. You can draw R16 from the Rectifier Unit "TUN" and R15 junction, to ground which will complete the schematic drawing. You can also see the same R15 and R16 "correctly drawn" on the TS-830 Rectifier Unit schematic. They do the same thing, form a series voltage divider for TUNE mode just as R5 and R6 on the HV Unit board in the TS-520 and TS-820 series transceivers do.

The low +130VDC you see at the 6146 screens, pin 3 on both 6146 tube sockets, is normal for TUNE mode. See the following explanation how this series resistor voltage divider works.

The 2 resistors, R15 and R16, are connected in series to form a resistor voltage divider to ground off the rectifier Unit's 210A supply.
R15 and R16 in series results in a total resistance of approximately 112K ohms to ground.

The 210A +245VDC supply output is applied to R15 and R16 resulting in a total current of 2.1ma flowing in both R15 and R16. You can calculate the current using Ohms Law formula
I = E / R
where "I" is the unknown current, "E" is the +245VDC, and "R" is the 112000 ohms series resistance of R15 and R16.

245 / 112000 = .0021 amps
The 2.1ma of current flowing through both resistors will result in a voltage drop of approximately +117.6VDC across R15.

.0021 x 56000 = 117.6 VDC
The voltage drop across R15 results in a DC voltage at the Rectifier Unit's "TUN" terminal and applied to the 6146 screens, pin 3 on each final tube socket, of approximately +127.4VDC which is normal. The voltage divider used in TUNE mode reduces the 6146 screen voltage by approximately 47% which results in a reduction in DC input power in the final amplifier in TUNE mode. The DC power input reduction in TUNE mode reduces the stress placed on the final tubes during TUNE mode transmitter tuning. Switching the MODE switch to CW, USB, or LSB will result in the return of the normal +245VDC 6146 screen voltage.

Hello Mike:I did all the calcs in my head and came to the same conclusions, (about half the rail voltage) what I did not know was what the screen voltage was suppose to reduce to in the tune mode as one of this group members told me it was suppose to be around 200 to 230 VDC. This is what did not make any sense to me. OK so now I guess I can assume the screen voltage is being reduced to the correct level and now back to, why I get no ALC when I am in the tune mode, regardless of how much I crank in the carrier control. Thank you for the information.Frank KD7HVL

You dont need SG voltage for ALC indication?? If that were the case how can you have ALC indication with the SG switch turned off?

For ALC indication in Tune mode you need:
1. 6146 cathode emission (not plate current)-- the heaters turned on
2. Normal operating bias voltage on the 6146 control grids (approx -60vdc)--Have you measured it to see if it transitions from approx -100vdc to -60vdc?
3. Normal RF drive level (greater than approx 43 rms rf volts) at the 6146 control grids to overcome the operating dc bias offset.

Have you measured the RF drive at 6146 control grids? Do it around 7.2 mhz as measurement probes will have lower capacitive loading effect on the Mixer and Drive tuned circuits. You need one of the following to measure RF drive:

1. VTVM and multi-diode RF probe
2. RF Millivolt meter
3. O-scope

Assuming that you have -60vdc operating bias when you flip to Send then you will need greater than approx 43 rms rf volts to see any ALC indication. 43 x 1.414 = 60.8. Around 49 rms rf volts will give you good full scale ALC deflection with no need for excessive CAR Level Pot advancement.

The 6146 control grids must be positive with respect to the cathode for micro-ampere (ua) grid current to flow and cause the ALC amp to pull the ALC bus control voltage down driving the meter upscale.

Numerous message on this forum describing what ALC is and how it is produced. Can also go to my website and read white papers on the subject.

SG divider resistors there for one purpose only and that is to protect Finals from high plate current caused by long keydown off resonance state when initially loading the radio. Nothing to do with ALC indication.

If you are going to be successful at troubleshooting RF drive problems with KW Hybrids you must have means to measure RF voltage and get familiar with the TX Level Diagram in the Service Manual.

Hello Terry:First off this is the first time I have been into a Hybrid kenwood or yaesu believe it or not. Second I posted the a request with the hope of getting a short cut of information to help zero in on the ALC problem with the group, figuring this problem had to come up. One of the members steered me to the resistor divider network dropping the screen voltage in the tune mode. I was informed the tune mode screen voltage was somewhere around 200 to 230 VDC far from what I measured. What got me here is miss information. I will go back at it Terry attacking it from your information. However considering it does make good power with no problems, does produce bias, and I do have plenty of RF drive, mic audio although producing full modulation on SSB seem to require mic gain set very high, full up.
  I will go to you site and read what you have to say about it. I am also confused what mic can be used as manual says high or low impedance is fine. That is a new one to me.
 Trying to explain why my mic gain has to be so high or if I have a problem there.Thank you for the response. TS 530 is in like new or almost new condition even smells like new, so I need to solve this or these problems.Frank KD7HVL

If you have 40 rms volts for example rf drive on the control grids and -60vdc operating bias you will make RF output power, but wont see any ALC indication when attempting to peak the Drive control.

In order to load the rig you would have to peak the Drive control on receiver back ground noise or peak it using the Marker signal or peak it using the RF relative power position. These are all work arounds. Some people live that way for years as they dont know how to correct the problem or have been convinced that it is normal especially on 10 meters.

Just because you have RF output power it doesnt mean you have maximum RF voltage swing at the 6146 control grids.

Only way I know to verify is to measure using one of the test instruments that I listed.

I dont want to hijack this thread. I just wanted you to know that 130vdc or 260vdc SG voltage isnt needed for ALC indication and to steer you to the TX Level Diagrams. Once you understand how to trouble shoot measuring RF voltage levels you can in matter of minutes isolate problem to a stage and then focus troubleshooting efforts there.

The question you need to answer is no ALC indication due to a lack of proper RF drive level or is it a fault in the ALC amp circuit or is it a metering problem (RL-1 contact). Faults in ALC circuit (Q31 AF board) are not common.

Not criticizing trying to help.

Mike and others can help. Dave VK5PDL has a lot of TS530 hands on experience.

OK but this kind of topic is how we all learn. Will close with this. I assume that the S meter works with off air signals and/or the marker signal?

If so, that means the meter FET and meter driver transistor are working and they are common as they monitor the AGC bus and the ALC bus depending on the state of RL-1 aux relay contacts.

Try one more test and you can then take on or off the forum as you desire.

If you have a 10 meg or 11 meg meter try to measure the ALC bus voltage at two places with SG switch OFF.
1. Measure at Audio Board at Molex Conn 9 Pin 1. Assuming RF-1 is set to 3.2vdc your volt meter should pull it down to approx 2.5vdc and drive the S meter up scale when rig is flipped to Send.
2. Measure at IF Board at Molex Conn 14 Pin 1. Should see same effect.

If the bus voltage pulls down and no meter deflection then the meter isnt seeing the voltage change on the ALM line. If you have two meters or can use a dummy resistor (1 meg or more) to load the bus you can watch the ALM pin at Conn 10 on IF board as you measure or load the ALC bus. When you see the ALC bus pull down to 2.5vdc should see ALM voltage go up from zero to a few 10ths of a volt (0.40vdc is max).

If bus voltage pulls down and ALM voltage goes up but S meter does not deflect up scale go to Audio Board Molex Conn 10 and short Pins 1 and Pins 2 after flipping to Send. If you get meter deflection then you have bad contact on RL-1 relay on IF board. Replace the relay with one of Ken K4EAA new relay boards with plug in relays. This relay is cause of many intermittent problems.

Hello All that have been helping me:Does anyone know if Kenwood still sells mode switches for the TS 530S. If I tap on the switch or rotate it real slow I can get a ALC reading equivalent to the 100 ma mark in both CW and tune. I can then vary the driver or the car pot and the ALC reading will track with the control. I also found a bad driver tube or at lest my tube tester says so. I replaced that. On 75 meters I am now getting 150 v p-p on a O scope 40 meters is a little less and I guess I need to re tune the slugs, 20 meters not much at all now. I think the switch is part of the problem. wires are very tight in that area of the mode switch, I looked for shorts or a broken wire and I could not find any. I see a diode there on the switch have to find it in the schematic and see where it goes.
 How often does a mode switch go bad??Frank KD7HVL

Hi Frank,

Are you sure that tapping and working the switch isn't just vibrating the radio and causing something else to go in and out.

If you really feel the switch is the problem, I would say you should work it back and forth a few dozen times and try to get the contacts to clean up a bit. If that doesn't do it, I would try to get some Deoxit into it before changing it. I think it's a sealed switch, but you may be able to get some in there, anyway.
This may be a lot easier than changing out that switch. If all else fails and you can't get one from walter.dilley@... , They are sometimes listed on Ebay.

Good Luck,
Kevin - N2FLP

Hi Kevin:

You are correct the switch decks are sandwiched and riveted tightly together (blue plastic body). Exercising multiple times is a good idea especially if the radio has set idle for long period of time.

I have looked for a NOS or sub replacement (not an exhaustive search)) from folks like Stackpole,Centralab, etc and came up empty.

You can take an artist brush and apply Deoxit D5 to the joints of the decks and hope that some will migrate or wick down between mating surfaces and reach the contacts. Gordon Benjamin N6WK told me that he had some success doing this. I have not had much success with that. It certainly cant hurt.

As you note the switch in not easy to swap out. Any used pull that you obtain needs to be measured on the bench and may not be any better.

You are correct that sometimes can get fooled into thinking where you are mechanically agitating is the source of the intermittent. Kind of unusual to have bad high resistance contacts in both the Tune and CW positions but possible. Far more common to have bad Bandswitch contacts or loose rivets.

If there is high resistance at the Mode switch contacts it means that the 9vdc that is supplied to the CAR Level Pot will be low by whatever IR drop occurs in the switch. That means that the 0 to 9vdc supplied to CV terminal on IF board will be low and then the 0.0 to 0.60vdc that is supplied to the Balanced Modulator ring diodes will be low and not turn the diodes on as hard which then means lower Carrier to the TIF amp.

I would use O-scope and monitor the TIF signal at the IF board as I exercised the Mode switch in Tune and CW. TIF signal is dirty due to VCO leak back from the TX Mixer and if you dont have modern scope can be a little touchy to get it synced and stable image. Normal TIF level would be around 12 to 15 mv rms or around 38 to 40 mv P-P. If you have a digital scope with internal filter set as Low Pass filter with 10 mhz cutoff and will get a nice clean image and steady voltage display on screen.

TIF is supplied to the TX Mixer on RF board where it ultimately becomes the RF drive at the actual transmit frequency. Frank reported that he had normal RF drive and RF output and I reminded him on previous response that normal would be approx 49 rms volts and if he had around 39 to 40 rms rf volts of drive he would have RF output, but NO ALC indication as 6146 control grids would never be positive with respect to the cathode on positive going peak of the drive envelope.

So it is possible if CV voltage applied from the CAR Level pot from the Mode switch is low that could produce RF output but not spec RF drive for full scale ALC indication. Unusual to have bad Tune and CW positions on Mode switch but of course is possible. An attempt to get some cleaner into it is worth a try.

I have thought about cutting the ends of the rivets off the back metal plate and removing it and then spraying contact cleaner in and then drilling a hole in the plate for future easy access and super gluing plate back in place. My luck it would all explode in my face!

Kevin have Merry X-mas and Happy New Year

Terry K9TW

Hi Terry,

I didn't want to say it because I thought some folks might think I was nuts, but if it were me and I knew the switch was the problem AND I could not get cleaner inside the unit as is, I would CAREFULLY drill a 'small' hole in the plastic at the bottom of the switch to get some cleaner in there. Drilling the bottom would allow any excess cleaner to drain. If the switch had reached the point of needing to be replaced, there really wouldn't be anything to lose in trying this step.
I'm sure many folks would not recommend drilling holes in their prized Hybrids, so I repeat, just cause I would try it doesn't mean anyone else should.

Merry Christmas and Happy Holidays to All!

Dave,

I mean no disrespect but may I ask a couple of questions?

1. Did the operator's manual come with the TS-520? If so, have you spent time studying the operator's manual before powering up your newly acquired TS-520. If the operator's manual did not come with your TS-520 then I recommend you download the manual, use the following link, and spend some time studying the manual before you attempt to receive and/or transmit using your TS-520.

http://w5rkl.com/manuals/

Scroll down the page and click on the operator's manual link for your model of TS-520.

I ask about the manual because quite often problems can be prevented if the operator/member would spend time studying the manual before attempting to operate their newly acquired KW hybrid.

2. What model of TS-520 do you have? The model of TS-520 can be found on the front panel below the VFO knob. There are 3 models of the TS-520.

Hello Martin,
Thanks for your reply. Yes I checked the received frequency on TS530 with the TX of another transceiver. So not only the display is wrong but also the effective Rx frequency. I will check the band signal, but the PLL seems to lock on every band as the display is active on all of them.

>
> Hi all,
> After change of Q14 on counter unit display and rx came back to life (see topic no display no RX after storage). But there is still a problem : On 1.5 3.5 24.5 Display and RX are OK. On the other bands, the display and RX work but are 500kHz lower than expected. I checked the VFO output : it is OK and between 5,5 and 6 MHz on all bands. On the bands were the RX is offset, the VCO output looks a bit strange with a double peak on top of the sinu! s signal.

Did you check this with a signal generator? The counter output has nothing to do with the real frequency. It always shows the VFO signal and adds a arbitrary offset to it. This offset is set by a matrix of diodes at the counter board. Plugs 4&5 at the counter board have lines for every switchable frequency and the diode arrays (and logical gates) on the board set the offset that is loaded into the counter for each switchable band.

So any problems with this diode matrix shows as difference between real RX frequency and value shown on the counter. I don't suggest this is the case with your rig, but you should look after it. Additionally, the PLL has several oscillators for the different bands that are switched with the same lines as the counter. These are in the upper left corner of the PLL schematic. The controller lines enter via plug 1@pll board. Check the voltage of these lines at this for all possible settings of the band switch. If there are controlling voltages missing at specific settings of the band switch the PLL doesn't work and the counter is dark. Additionally, exactly one)and only one!) of the wires coming into the PLL via plug 1 must be active. I had similar problems with my TS830S (some positions of the band switch had no RX and a dark display), this was easily tracked to shorts between some lines of plug 1. On some settings more than one line was active and the correct oscillator wasn't working... The counter display gets dark when no PLL lock is found.

Martin

Jean,

You said

/*"*//*I checked the VFO output : it is OK and between 5,5 and 6 MHz on
all bands.*//*"*/
*
That's correct. The VFO output frequency range is the same, 5.5Mhz to
6.0Mhz regardless of the band switch setting.

You also said:

"**/the display and RX work but are 500kHz lower than expected/."

I doubt the TS-530S VFO is off "500Khz". If it were then the receiver
wouldn't work, the VFO frequency tuning range would be wrong.

I think you meant to say the display is off "500Hz".

There are 1000 Hertz (Hz) in 1 Kilohertz (Khz). There are 1000 Kilohertz
(Khz) in 1Megahertz (Mhz).

Jean

Have you measured the 500khz reference clock to Q17 PD and the 500khz feedback pulses to Q16 1/N divider? Should see approx 4 to 4.5 v P-P at Q16 pin 15 and at Q17 Pins 1 and 3.

Also, have you measured the VCO output frequencies to see if off by 500khz and if so have you measured the Vari-cap line voltages to see if they are off. Step 9 of the Service Manual has the table for DC control voltages per VFO settings of 0, 250 and 500 and the VCO frequencies.

For example read dc control voltages and VCO frequencies for example on 20 meters at 0, 250, and 500 off the analog dial and report findings.

Terry K9TW

Thanks Wally and Dave for replies,
Some progress using your info but still not complete :- In fact 28.5 and 29.5 are also OK. So all bands with "A"=0 are OK- I checked DCBA at the output of Q14 : "A" was low on all bands. A circuit track was broken from Q14 pin 10 to R20/R24. I replaced it. "A" is OK now changing from band to band according to the table.- The RX frequency is OK but the display is still 500 kHz too low on all bands except 1.5 3.5 24.5 28.5 29.5.
Still looking.

Hello Mike,

Indeed the display is 500 kHz (kilohertz) too low on some bands (all except 1.5 3.5 24.5 28.5 29.5). I had a problem on the counter board with the input for "A" of DCBA on Q14. It is fixed now. The real RX frequency is OK (checked with TX of another transceiver)but the display is still 500 kHz too low (ie when tuned at 7.0 MHz with the mechanical dial I receive 7.0 Mhz but the display is 6.5 MHz.

I unadvertedly created two threads on the same topic. Please join your possible next comments to the other one.

Thanks for your help Mike,

According to the table at pg. 5 of the service manual the bands 1.5, 3.5, 24.5, 28.5 and 29.5 (and only these bands!!!) have one thing in common: the "0.5" line is "H". At all other positions of the band switch this line has to be "L". You can check this at the central pin (#6) of the ext. VFO plug. This pin has to go from 0V to about 5V when switching bands at 1.5, 3.5 etc. If this happens, the culprit is at or behind Q14.

You already checked Q14 and "A" line (at plug 2 Pin 7) is changing according to switch position. However, the interesting part is the line from the output of the inverter (Q14, pin 10) to Q8, pin 6. Q8 has 4 AND gates, the relevant one has its inputs at Q8 pin 5 and 6, the output is 4. Does Q8 pin 6 changes voltage when you turn the band switch? Check continuity between Q14,10 and Q8,6. Chances are good that this is open...

If the connection between Q14,10 and Q8,6 is good, measure the output of the Q8 gate at Q8,4. It must be low if Q8,6 is low (an "AND" gate is high only when BOTH inputs are high, so any low level at Q8,6 or Q8,5 must give low at the output Q8,4). With TTL gates, an open input counts as "HIGH". I'm not quite sure how these CMOS gates behave, but I think its the same.

Martin DB2MJ (with fond memories of truth tables, Quine-McCluskey calculations and big TTL circuits some 35 years ago...)

Well done Martin (and Dave, Wally, Mike and others) !
The connection between Q14 10 and Q8 6 was also broken. Most probably I could not recover it when changing Q14 : it is below the IC on the upper side of the board, as the previous one I had to fix. I strapped it and now the display is correct, in accordance with the effective RX frequency.
The RX of the TS530S is now fully operating.
Now to test the TX part...Thanks to all for this very instructive process.

Good morning everyone, my name is Joe and I'm new to the group. I have a TS-820S. I have a few questions. I just picked up this radio with no mic. I have been listening and picking around for about two weeks. When I first started moving through the vfo it would drop a digit here and there.
After it warmed up it seemed to clear up. My microphone arrived yesterday and I noticed a change while transmitting.
Once I started transmitting I dropped every other digit. And it stayed like that for the rest of the day. This morning I have all of my digits back, with the unit cold. (I have no idea if this is related to heat). I live in NY on Long Island. Can anyone recommend a reputable person or a shop that can take a look at this new to me rig. I also have the SM-220 I would like to have checked out as well. I am brand net to the hobby and currently have a tech license. (working on getting general).
Thank you in advance

Derek,
  It's possible that you may have a malfunctioning relay(2)/Q10. It's been quite sometime since I had a 520 on my bench. One relay is on the underside of the chassis next to the final amplifier board, under the metal plate that the bandswitch goes to. The other, I believe is under the "VOX" board...on the top, left rear of the chassis. You stated that power supply, reduced screen voltage in tune, plus cathode & screen resistors are OK. It would be nice if you listed the values that you have at each of these points.
  You stated in another msg, that the driver and finals are new. Why were they changed? A very simple test to see if the 12by7a driver is strong is to load up the rig on the highest band, and see if you can get full meter deflection in ALC using the "CAR" control. A white paper done by a long time group member, Terry-k9tw, my be helpful to you:

Joe,
Welcome to the group and the (unfortunately) common problem with the TS-820S DG-1 unit. If the unit seems to work Ok when cold, then acts up when warm, indicates that a connection is opening when warm. I take it that when the display acts up...it does not affect the overall operation the the rig...ie it still receives fine? It's up to you, but sending the rig out for repair may a bit cost prohibitive. Do you have a local radio club that may be able to help? You can start with (if you feel comfortable) by getting some contact cleaner, and a can of "canned air" aka "air duster" You can try and clean the multi-pin connector on the underside of the DG-1 with the contact cleaner first. to see if that helped. You will have to remove the DG-1 unit from the rig and disassemble it to clean all the other connectors. The major flaw is the "through holes" or "vias" that go through from one side of the board(s) to the other...these are just holes that have solder in them, and over a period time my become intermittent or just totally fail. The problem was such a problem, that Kenwood issued a Service Bulletin regarding it. It involves a bunch of small diameter wires, a low watt soldering gun/iron, magnification, bright light and patience as there are 18 of these "holes" to rework.
Check out this web site:http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm scroll down to the bottom. there are some repair guys listed.

Hi Joe, I get no alc deflection whatsoever! I don't remember exactly what

the screen voltages were but they were close to the values in the service manual. I checked the tubes on my b& k tube tester which checks 6146's also. The driver was bad in the set but the 6146's tested ok. The rf on the plate of the 12by7a is supposed to be 50 plus volts (screen off). I measured about 20 volts with my tektronix tds 700d oscilloscope. While reduced I would think I would see some alc and I see none at all! The alc point on q10 only measures 3 vdc in receive and in transmit with no change. The service manual did list bad relays as a reason for no alc. It also lists a bad q10. I hope that is not the problem as the wire wrap connections on the rf board would make removal and repair a nightmare! Does this help? It would be interesting to see how the 520s operates with one or both relays bad. Thanks for your interest. 73's Derek K9fqo

Derek:

A few things:

1. Did you measure the DC voltages at the Pins of the Driver tube and Final tube sockets and not just measure the Power supply voltages? Does no good to measure power supply voltage and not measure where the tubes like to use things like operating bias and screen grid voltage. If you dont have Pomona test socket for the Driver tube just pull the tube and measure at the tube socket pins from top side.

2. Pretty much disregard the Troubleshooting charts in any of the KW Hybrid manuals. They are all pretty much worthless. No KW bench Tech would ever reach to replace Q10 as a first or early on repair step as the root cause for no ALC indication. Fortunately active devices dont fail that often. Same as you would not replace RF amp dual gate mosfet as a first or early step when have no or weak receive. Likewise very seldom will you ever find a bad wire wrap on any of the terminal post. Might find broken solder joint at base of post from time to time, but wire wraps are very good low resistant gas impervious connections.

3. You started down the right path by running the TX Level diagram and measuring the RF drive level at Plate of the Drive tube. I assume you then backed up from the Plate of the Driver to the output of the TX Mixer when you say that you only had 20 volts drive? I also assume that when you saw this you tried another known good Driver tube and measured the Driver tube dc voltages at the tube socket? Also is your measured RF drive of 20 volts being reported as rms or P-P? Good level will be approx 55- 60 rms rf volts or approx 150 to 160 P-P rf volts.

Dont use the rf drive voltage levels listed in the TS520S service manual. They are wrong and not based on dual S2001A or 6146 final tubes or 100 watts output into dummy load at 14.175mhz. Use the TX Level Diagram values listed in the TS520 service manual.

You may want to run the TX Level Diagram at 7.2mhz to reduce the capacitance loading and detuning effect that your O-scope probes may present to the Mixer and Driver tuned circuits. May have to adjust the Drive control for any detuning effect that probe presents.

4. Lastly why would you think you should see any ALC indication if you only have 20 rms RF volts at the Plate of the Driver tube or even less on the 6146 control grids (measured at Pin 5)? To have any ALC indication the Final tube control grids must be positive with respect to the Cathode to have ua grid current flow for Q10 to act on. No grid current means the ALC bus voltage wont be reduced and the S-meter FET monitoring the bus wont see any lowering of the bus voltage to act upon.

Assuming you have set the zero signal plate current to close to 60ma you should see approx -55vdc to -60vdc operating bias on Final tube control grids. The RF drive signal from the Plate of the Driver tube must overcome this dc offset on the positive going peaks of the drive envelope. 60 x .707 = 42. With 42 rms or 120v P-P rf drive voltage on the control grids they are not yet positive with respect to the cathode. 20 volts wont cut it if 42 volts brings you to zero delta between the control grids and the cathode.

So assuming you have -60vdc operating bias when you flip to Send you must have greater than approx 42 rms or 120v P-P rf volts to see any ALC indication on the meter. For good full scale ALC deflection you will need 47rms to 49 rms RF volts. 47 x 2.828 = 133 rf volts P-P. With 20 volts you have a long way to go to overcome the zero offset. Remember the RF sine wave of the drive signal is not swinging around the zero axis.

Summary:

If you have not measured the Driver tube and Final tube dc voltages at the tube socket pins when flipped to Send (with emphasis on operating bias and screen grid voltages) then do so. Next measure RF drive at 6146 control grids and work your way back to the TIF signal on RF board. Some folks start at TIF and others start at the Finals. Makes no difference. Where you find RF drive low or missing is where you then focus your troubleshooting efforts. I am also assuming you have measured RF-1 (ALC bus reference voltage) at the RF board wire wrap post and set it to 3.3vdc. I am also assuming you have set resting plate current to 60ma.

Lastly, if you have never looked at TIF it can be a little confusing as it will have harmonic content from leak back from the strong VCO signal present at the TX Mixer. Fortunately TIF is seldom a problem other than it is not uncommon for people to have messed with the TX band pass filter that is partially on the IF board and partially on the RF board. If you find TIF low dont mess with the cores T3,T4, T1 until we discuss a method without a sweep gen or spectrum analyzer.

Hi Joe.
Welcome to the group.
As Joe, WB7UQU suggests, is a typical problem of TS820S.
I had the same problem and the final solution to clean all contacts DG-1 unit and also review the welds of the 18 holes interconnect the two sides of the PCB carrying integrated circuits, besides solder connectors connecting both plates.
This requires removing the DG-1 chassis unit by removing the four screws at the bottom there and then remove the screws holding the cover. You will see that there are two plates, one with IC's, which is what has to review.
You should also clean the contacts that connect this board with the other.
In "photos", you can see a picture in which are marked the famous 18 holes. You have to put a little thread to ensure contact between both sides.
It is a delicate job, but a welder with pointed tip, good light and patience is needed.
So definitely solved the problem.
There is something more, it is very important the grounding of this board. I put a wire jumper for it.
Best regards from Spain.

53738. HYBRID NET UPDATE (December 27, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-12-28 00:45:42 UTC
From: Mark Gilger
Topic: 53738 Message: 53738

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

There was no Saturday net due to the holidays.

The Sunday net was run by me, WB0IQK. There were
21 stations checking in under good conditions.

We had the following number of radios checking in.

3 running TS-520(x)
2 running TS-530(x)
4 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-520s + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals

plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins
Nov. 2014 ☐ Oct 2015 Saturdays total 962 check-ins, Sunday total 669 check-ins

November 2015, Saturday☐s net total = 66, Sunday☐s total = 46
December 2015, Saturday☐s net total = 55, Sunday☐s total = 73 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

Topic: 53739 Message: 53740

Jose:

Do you have a frequency counter?

If so, connect it using 10x scope probe to TP-3 on IF board and see where the 455 khz oscillator is set at. If you read around 451 khz that is your problem. This is common error and not getting the mic audio into the ceramic filter passband.

Adjust trimmer capacitor TC-4 for around 452.5 to 453.5 khz on your counter and see if that makes a difference. Listen on the Moni and watch the Comp meter to see if now improved with normal voice and Comp level pot at 1200.

What I just gave you is quick and dirty fix. Better to do a complete processor alignment. For that you will need a good Audio generator and means to measure RF voltages at TP-2.

Terry K9TW

53741. TS530S : Trouble to tune TX

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-12-29 11:24:45 UTC
From: Jean Louis Maridet
Topic: 53741 Message: 53741

Hi all,
With the help of the group I could fix my TS530S on RX. Now I tested it on TX. I get HV, IP, ALC values which seem correct but the plate tune is not at the expected band indication, quite far away on some bands, even out of written range. The output power is not as expected too (30-40W), and the dips look not so deep than before.
In the RX fixing process, I had to change the band switch shaft which got loose and broke. I tried to put it back in the original position but I have a doubt about it.
Can anyone tell me how to be sure that the band switch axis is aligned on both the foreground part (RF board) and the background (final cage)?

Thanks for your help, hapy new year to all,

Attachments: 2 described; binary payloads are missing from this source WARC

Jean,

Remove ALL power, let the 530 sit so the power supply filter capacitors have discharged to zero.

Remove the top and bottom covers.

Remove the final amplifier cover.

Remove both 6146 tubes.

You will have to loosen the coupler between the RF Unit band switch long shaft and the band switch shaft inside the final amplifier.

Do NOT pull/remove the long band switch shaft from the RF Unit switch wafers!!! It's okay to pull the shaft back just enough to remove the bad cracked coupler.

The shaft on the band switch "inside" the final amplifier has 2 flat spots, 90 degrees of each other. See the following picture to see the flat spots on the final amplifier band switch:

The arrow in the picture below is pointing to the final amplifier band switch coupler that cracks. The shaft on the band switch the arrow is pointing to has the 2 flat spots shown on the picture above.

Rotate the band switch inside the final amplifier so the flat spots are at the exact locations indicated below.

1. Rotate the final amplifier band switch shaft so one flat spot is exactly "vertical" and facing the right side of the final amplifier where V1 6146 is (front 6146).

2. The other switch shaft flat spots should now be facing directly down at the chassis (exactly horizontal).

Make sure the flat spots are oriented exactly as stated above.

Install the new coupler and slide the long shaft into the coupler.

Do not tighten the coupler set screws.

Rotate the front panel band switch so the band switch knob is pointing exactly at "10" (30 meters), NOT 10 meters!!!

Verify the above settings. If all are as stated, tighten the coupler set screws. You are done.

Replace the 6146 final tube, final amplifier cover, and both top and
bottom covers. Test the radio for proper operation.

I believe that there is a flat edge on the shaft that needs to be aligned with one of the screws.

Subject: Re: [TS-520_820_530_830] TS530S : Trouble to tune TX

Jean,

Remove ALL power, let the 530 sit so the power supply filter capacitors have discharged to zero.

Remove the top and bottom covers.

Remove the final amplifier cover.

Remove both 6146 tubes.

You will have to loosen the coupler between the RF Unit band switch long shaft and the band switch shaft inside the final amplifier.

Do NOT pull/remove the long band switch shaft from the RF Unit switch wafers!!! It's okay to pull the shaft back just enough to remove the bad cracked coupler.

The shaft on the band switch "inside" the final amplifier has 2 flat spots, 90 degrees of each other. See the following picture to see the flat spots on the final amplifier band switch:

The arrow in the picture below is pointing to the final amplifier band switch coupler that cracks. The shaft on the band switch the arrow is pointing to has the 2 flat spots shown on the picture above.

Rotate the band switch inside the final amplifier so the flat spots are at the exact locations indicated below.

1. Rotate the final amplifier band switch shaft so one flat spot is exactly "vertical" and facing the right side of the final amplifier where V1 6146 is (front 6146).

2. The other switch shaft flat spots should now be facing directly down at the chassis (exactly horizontal).

Make sure the flat spots are oriented exactly as stated above.

Install the new coupler and slide the long shaft into the coupler.

Do not tighten the coupler set screws.

Rotate the front panel band switch so the band switch knob is pointing exactly at "10" (30 meters), NOT 10 meters!!!

Verify the above settings. If all are as stated, tighten the coupler set screws. You are done.

Replace the 6146 final tube, final amplifier cover, and both top and bottom covers. Test the radio for proper operation.

Rotate the band switch inside the final amplifier so the flat spots are at the exact locations indicated below.

1. Rotate the final amplifier band switch shaft so one flat spot is exactly "vertical" and facing the right side of the final amplifier where V1 6146 is (front 6146).

2. The other switch shaft flat spots should now be facing directly down at the chassis (exactly horizontal).

Make sure the flat spots are oriented exactly as stated above.

Install the new coupler and slide the long shaft into the coupler.

Do not tighten the coupler set screws.

Rotate the front panel band switch so the band switch knob is pointing exactly at "10" (30 meters), NOT 10 meters!!!

Verify the above settings. If all are as stated, tighten the coupler set screws. You are done.

Replace the 6146 final tube, final amplifier cover, and both top and bottom covers. Test the radio for proper operation.

Luther,
The amplifier's relay connection is between the TS-520SE's 8 pin socket's pins 1 and 5, 1 being ground and 5 being "N.O" (Normally Open) relay terminal. When the TS-520SE switches to transmit, relay pins 1 and 5 connect resulting in the amplifier relay to "energize" and switch the amplifier into transmit. Switching back to receive, the TS-520SE's relay is no longer energized resulting in pins 1 and 5 no longer being connected, hence the amplifier's relay is no longer energized and the amplifier switches to standby. Pins 1 and 5 on the TS-520SE act as a simple SPST switch, just as the wall switch in your home turns the light ON and OFF.

The amplifier to TS-520SE ALC connection is between pin 6 and the amplifier's ALC connection. Read the amplifier's manual on the ALC connection. Some amplifiers have a pot that's adjusted.

Jean and others,
That procedure is not found in any manual that I am aware of. The same procedure applies to the TS-830.

I'm glad you were able to fix your problem by performing the BNAD switch alignment.

Subject: Re: [TS-520_820_530_830] TS530S : Trouble to tune TX

Jean,

Remove ALL power, let the 530 sit so the power supply filter capacitors have discharged to zero.

Remove the top and bottom covers.

Remove the final amplifier cover.

Remove both 6146 tubes.

You will have to loosen the coupler between the RF Unit band switch long shaft and the band switch shaft inside the final amplifier.

Do NOT pull/remove the long band switch shaft from the RF Unit switch wafers!!! It's okay to pull the shaft back just enough to remove the bad cracked coupler.

The shaft on the band switch "inside" the final amplifier has 2 flat spots, 90 degrees of each other. See the following picture to see the flat spots on the final amplifier band switch:

The arrow in the picture below is pointing to the final amplifier band switch coupler that cracks. The shaft on the band switch the arrow is pointing to has the 2 flat spots shown on the picture above.

Rotate the band switch inside the final amplifier so the flat spots are at the exact locations indicated below.

1. Rotate the final amplifier band switch shaft so one flat spot is exactly "vertical" and facing the right side of the final amplifier where V1 6146 is (front 6146).

2. The other switch shaft flat spots should now be facing directly down at the chassis (exactly horizontal).

Make sure the flat spots are oriented exactly as stated above.

Install the new coupler and slide the long shaft into the coupler.

Do not tighten the coupler set screws.

Rotate the front panel band switch so the band switch knob is pointing exactly at "10" (30 meters), NOT 10 meters!!!

Verify the above settings. If all are as stated, tighten the coupler set screws. You are done.

Replace the 6146 final tube, final amplifier cover, and both top and bottom covers. Test the radio for proper operation.

Hi Jean-Louise,

On the RF board the band switch wafers have a dot on them which will help you with alignment. The W0NTA site has a document which describes this, with pictures. The link is here: http://w0nta.com/Rebuilding%20the%20bandswitch.pdf This is his article on rebuilding the bandswitch which should be of assistance.

I hope this helps you with your TS-530S.

73,
Joe N9JR

You're welcome Luther.

I use audio shielded cables to make the connection. audio/video cables
that come with DVR/DVD and VCR players/recorders works well for this
connection. The typical amplifier relay DC voltage that will be applied
to the cable is 12VDC with a current rating of 100ma or less.

Subject: Re: [TS-520_820_530_830] TS530S : Trouble to tune TX

Jean,

Remove ALL power, let the 530 sit so the power supply filter capacitors have discharged to zero.

Remove the top and bottom covers.

Remove the final amplifier cover.

Remove both 6146 tubes.

You will have to loosen the coupler between the RF Unit band switch long

shaft and the band switch shaft inside the final amplifier.

Do NOT pull/remove the long band switch shaft from the RF Unit switch wafers!!! It's okay to pull the shaft back just enough to remove the bad cracked coupler.

The shaft on the band switch "inside" the final amplifier has 2 flat spots, 90 degrees of each other. See the following picture to see the flat spots on

the final amplifier band switch:

The arrow in the picture below is pointing to the final amplifier band switch coupler that cracks. The shaft on the band switch the arrow is pointing to has the 2 flat spots shown on the picture above.

Rotate the band switch inside the final amplifier so the flat spots are at the exact locations indicated below.

1. Rotate the final amplifier band switch shaft so one flat spot is exactly "vertical" and facing the right side of the final amplifier where V1 6146 is (front 6146).

2. The other switch shaft flat spots should now be facing directly down at the chassis (exactly horizontal).

Make sure the flat spots are oriented exactly as stated above.

Install the new coupler and slide the long shaft into the coupler.

Do not tighten the coupler set screws.

Rotate the front panel band switch so the band switch knob is pointing exactly at "10" (30 meters), NOT 10 meters!!!

Verify the above settings. If all are as stated, tighten the coupler set screws. You are done.

Replace the 6146 final tube, final amplifier cover, and both top and bottom covers. Test the radio for proper operation.

Hi all,

With the help of the group I could fix my TS530S on RX. Now I tested it on TX. I get HV, IP, ALC values which seem correct but the plate tune is not at the expected band indication, quite far away on some bands, even out of written range. The output power is not as expected too (30-40W), and the dips look not so deep than before.

In the RX fixing process, I had to change the band switch shaft which got loose and broke. I tried to put it back in the original position but I have a doubt about it.

Can anyone tell me how to be sure that the band switch axis is aligned on both the foreground part (RF board) and the background (final cage)?

Thanks for your help, hapy new year to all,

Greetings group,
Well.....another year is at an end(almost) and, it's already a New Year for some group members. The group has added many new members, and has also lost a few over this year. I hope that many rigs that were possibly headed for the junk pile, ended up being fixed and put back into operation with the help of this group. I especially want to thank Terry-k9tw, and Mike-w5rkl, for their knowledge and contributions to the group, and everyone else that helps keep the group afloat, and these old rigs working well past their prime.
Also, thanks to Mark-wb0iqk and Jimmy-wb2knr for operating net control for the KW hybrid net, Walter-kd7dny, for buying Bob-ke5ftf's parts inventory. There are many others, so, PSE don't be offended if I forgot you.
On behalf of myself, Walt(your benevolent overlords/group co-owners), Ellen and Jon(assistant overlords/group moderators).....

    A very Happy New Year, and a prosperous 2016. PSE take a few moments to think of our Military Service Members who can not be home.

Derek:

Your DC voltages look good to me. You are getting cutoff bias to switch to operating bias on both the Driver tube and Finals and the Screen Grid voltages looks good.

Of course 50v P-P rf drive to Control Grid Pin 5 of the Finals is very low. Should see from approx 130v to 150v P-P. Drive level at control grid of 12BY7A is also low. Should see approx 5v to 7v P-P at MD or TP-1.

Did you say that output power was low on all bands into the dummy load? Did you try another known good Driver tube? You may have previously mentioned these two items, but I have slept since then!

Can also do a Driver tube test as follows:

1. Turn off the SG switch, leave heaters on, CW mode, meter in ALC position
2. CAR pot at 1200
3. Flip to Send and peak the Drive Control; Should see Full Scale ALC deflection on all bands with exception of 10 meters. If meter pegs simply reduce the CAR pot to get indicator off the peg. Should be able to peak at FSD and hold there a few seconds and not see any fall off of the needle. Rest 10 seconds or so between bands when doing this test as Driver Tube is running Class A pretty close to max plate current.

Also, the power should not fall off when advancing the CAR Level pot. Measure the DC voltage at CV terminal post on the Gen board from full CCW to full CW on the pot. Should see smooth change approx 0 to 9vdc. Then measure at BM post on Gen board. Should see approx 0 to 0.50 vdc. As you open the pot you should be turning on the diodes of the BM harder producing more carrier which means more TIF level.

Lastly, since you see low RF drive at MD and TP-1 (output of the TX mixer) go back to input of the TX Mixer at TP-2 on RF board and measure the TIF drive level. Should be approx 500 mv P-P and remember I think that I told you previously it wont be pretty due to Het Osc leak back.

Thanks Terry, I will look at the levels. The driver and final tubes are ok. I tried different tubes with the same results plus I have a b&k tube tester that will check 6146's! I see poor output 10-20 watts on all bands and no alc on any. I will look at CV and BM terminals. My knowledge and experience is very limited with this vintage. I am blessed with near state of the art test equipment however. I have a tektronix real time spectrum analyzer model RSA 3408a which may be very helpful! Thanks Derek K9fqo

Derek:

The only way I know how you could have 2v P-P 8.6mhz at TP-2 when flipped to Send and Drive Control peaked for max ALC indication (in your case since no ALC then max RF relative power or max RF drive at MD or TP-1) is for Q1 TX Mixer (sits in socket right next to TP-2) to be bad or removed from its socket. Normal drive will be approx 500mv to 600mv P-P at TP-2 and not 2v P-P.

Suggest you measure the DC voltages at Q1 DSG1G2. Perhaps Q1 has been improperly subbed? Leads improperly transposed? I dont know if radio ever worked properly in your possession with this Q1 installed as it is?

You can also measure the TIF signal at the TIF wire wrap post on RF board when flipped to Send. It will be approx 80 to 90mv P-P at 8.6mhz.

Typically if you find abnormally high RF drive voltages when running TX Level diagram it means that the signal isnt seeing the next load ie resonant circuit or control grid or gate. For example you should see about 8v P-P at TP-1. If you pull the 12BY7A Driver tube TP-1 will jump up to approx 25v P-P rf drive because the the input impedance that the control grid presents to the output of Q1 TX Mixer is removed ie essentially gone infinite.

Summary:

1. What is the TIF drive level?
2. Is Q1 Het Mixer (TX Mixer) original 3SK41 or a sub?
3. What are the DC voltages at Q1 leads in the socket?

Your CAR Level Pot is working as it should based on your BM dc voltages. For now we can assume that the BM is working and good TIF level at input of BPF on IF board.

Happy 2016 to all.

Derek:

I forgot to ask Do You have a good RF signal generator?

If so, you can pull Q1 TX Mixer and then drive the transmitter with your RF Sig Gen at TP-1 on the RF board. Use a .001uf or .01uf or .047uf coupling cap (value not critical just need dc block).

Apply approx +18dBm or 1.75 rms rf volts or 5 rf volts P-P to TP-1 and then Flip to Send (need to terminate your Sig gen with 50 ohm feedthru). Should see 100 watts into dummy load and see good peak in ALC. If all of that works with your Sig Gen supplying the 7.2mhz rf drive instead of Q1 supplying it then you know transmitter is capable of 100 watts out and that ALC circuit is functioning as it should.

If this doesnt work then I would look for a bad solder connection at the 12BY7A Driver tube socket pins (especially at control grid pin). Not likely as you had good DC voltages on all the tube socket pins. You can press and pull and wiggle the Driver tube with RF drive applied and see if RF output comes and goes. Use rag on the black shield can so dont burn fingers and dont go crazy with application of force.

Very rarely the C49 interstage coupling cap is bad, but it can happen.

Lastly for Q1 TX Mixer to work in addition to correct DC voltages you need high level of Het Oscillator as the Local Oscillator (LO) for the Mixer. Unusual for HET level to be low on all bands. Use your scope and measure HET level at TP-3 and at G1 of Q1. HET will be approx 4.5 to 5.0 rf volts P-P at 15.895mhz at TP-3 and around 4.0 volts P-P at Q1 socket at G1 lead.

I measure 4.0 volts at TP 3 and 3.8 volts at g1. pretty much same on all bands. Derek K9fqo

Hi, Here is what I have found so far TP2 rf board is 4 v p-p, tif 400 mv
p-p tp1 2 v p-p. q3 mixer. Source r 71mv, t 3.95 vdc,
g1 r -4.22 t 2.72 vdc, g2 r 11.2 vdc. t 10.9
(lose output when measuring), drain r 14.5 vdc, t 13.99 vdc (lose output).
Next I pulled q3 mixer and applied 12.6 dbm 7.2 mhz signal to tp1. I got
90 watts out but no alc ! 12.6 dbm is the max my generator will do. ?

Should be approx 200mv P-P at TIF wire wrap post.

It doesnt look like TIF is seeing Q1.

Where is the tab on the mosfet pointing? Should be pointing around 4:00 oclock looking down on device case from the top.

You could try pulling Q2 and place it in Q1 socket (dont swap them).

Makes no sense at all as both are the same place electrically? Need to make sure on correct test points and re-measure. MD and TP-1 should be approx 7v P-P with SG switch on or off.

I assume you are using a 10X scope probe?

I thought this was a TS520S and not a TS520???

If you pulled Q3 then I have been talking about a TS520S which the TX Mixer is Q1???

I recall telling you to ignore the TS520S TX Level diagram and to use the TS520 and I dont recall you correcting me that rig was not a 520S?

You dont want to inject high level of RF at TP-1 on the TS520!

TP-1 is a very different test point between the two rigs. TP-1 on the 520S is same as MD.

Terry, The tab looking down from the top standing in front of the Kenwood is at 1 pm. Is this correct? I am using a tektronix p6339a buffered passive probe 10mohm, 8.0pf probe which is specifically designed for my tektronix tds 794d.
I am sorry this is a kenwood ts 520 not 520s. I measure 2 v p-p at tp1 and 4 v p-p at md with SG on or off. Very sorry for the confusion. thanks
Derek K9fqo

Should be approx 200mv P-P at TIF wire wrap post.

It doesnt look like TIF is seeing Q1.

Where is the tab on the mosfet pointing? Should be pointing around 4:00 oclock looking down on device case from the top.

OK the TS520 and the TS520S are very different radios in several key areas. The subject line looks like a ts 520s to me.

Pretty much disregard my previous responses. I really need to get back to the bench. I had a cancellation so had a window to try and help here for awhile, but need to move next radio in line up and get started on it now that my holiday break is over.

Are you looking at Q3 TX Mixer? If so, the location notch on the socket and the mosfet can tab should be at the 1200 position. Should be no lead transposition.

You dont want to measure anything at TP-1 or inject test transmit RF drive at TP-1. TP-1 on the TS520 is not an RF drive transmit measurement or injection test point. It is a test point to inject Sweep Gen input for receiver band pass filter (BPF) alignment. Disregard anything in my previous responses about TP-1. If you do inject test RF drive at TP-1 when you connect your RF sig gen in RX mode it will feed Q4 RIF Mixer and peg the S-meter very hard.

Do you have the TS520 Operators manual? If so, it has a active device voltage chart near the back where you can see the DC voltages for Q3 on RF board (D,S, G1, G2) if it turns out there is a need to measure them.

From my notes here are the RF drive levels that I have recorded for a TS520 that had full 100 watts output and full ALC indication with the SG switch off, Drive control at 1200, and the CAR Level pot at 1200 (7.200 mhz):

1. TIF (8.695mhz) at TIF post = 400mv P-P (140mv rms)

2. TIF at TP-2 post = 2.0v P-P (700mv rms)
3. MD (7.200mhz) at MD post = 6.5v P-P (2.3v rms)

I dont have an operational TS520 here to take any measurements for you.

If you get stuck might contact Jimmy WB2KNR. He specializes in servicing TS520 rigs only and owns a fleet of them and I suspect always has the covers off of a fully operational one. His contact info is in QST magazine.

Hi all, questions. I just picked up a second hybrid.
The TS-830s, gold I believe
I can tune the tubes (peak and dip) for output on 20 meters. But not on 10 meters. No meter movement. Any ideas?? Thiis is a problem as I hold only a tech license and can only xmit on 10 meter

Joe,

this may indicate a soft driver tube. Turn car fully clockwise, go to 28.800, turn 25khz on, adjust drive control to give max receive reading. Turn cal off, place radio in tune mode, flip send switch on, and try and peak drive for max alc reading then adjust plate and load for max output. Send switch off, mode to cw, meter to alc, send switch to send, very quickly adjust car control to max alc meter reading. Quickly adjust plate and load for max output. With meter in alc, watch needle, to see if it drops.
As the PA will be at max output, this should only be in transmit mode for max 5 seconds. If needle starts to drop, a good indication of soft driver tube

Joe this is not true !~!Actually you can also transmit CW on 80, 40, 15 and 10M With a Tech License!You Just have to take a few days to learn the 26 letters, 10 digits and a few punctuation symbols (. , ?) Then you have access to a lot more relialble propagation than 10M has now ! My radio is Ham Radio...CW is Real Radio 73, John...K8JD

Joe,

It appears you may not know or understand what authorized frequencies
and emissions your Technician class Amateur Radio license allows you to
operate on.

I recommend you click on the following link to download FCC part 97
Rules and Regulations that govern Amateur Radio operations in the U.S.
and it's territories.

http://w5rkl.com/wp-content/uploads/2015/02/FCC-Part-97-Amateur-Radio-Rules-and-Regulation
s.pdf

Once you download the FCC part 97, I recommend spending time
reading/studying part 97, paying attention to the following sections
that outline the authorized frequencies and emissions for your
Technician Class Amateur Radio license:

97.301(e)
97.305(c)
97.307(f9)

The only HF band you are authorized to operate "voice" mode is 10 meters
and only between 28.3Mhz to 28.5Mhz. A Technician class Amateur Radio
license is not authorized to operate FM or AM on any HF band.

Hi friends.
I installed some time in my Kenwood TS820s filter YG-88C, for CW and also have a TS450S as the YK-88C filter for CW ago, I noticed a difference in the reception of both radios.
This can be seen in the pictures I uploaded my album.
In photo 1 the bandwidth of the filter is observed TS450S.
In photo 2, the bandwidth of the filter without changing the command TS820S IF SHIFT
And in the photo 3, bande width varying filter TS820S IF SHIFT control
Is this normal or any adjustment should be made to install the IF filter?
Thank you very much for reading and Happy New Year.
Best regards from Spain
Rafa.

Rafa,

Instructions to install the CW filter in the TS-820/TS-820S is found in the TS-820S Instructi8on manual on page 34 titled

"6.3 ACCESSORIES

INSTALLING THE CW FILTER (YG-88C)
(SEE FIGURE 25)

Steps 1 through 4

Figure 25 is on page 34.

Instructions to install the CW filter in the TS-450S are found in the TS-450S_TS-690 Instruction manual on page 81 titled:

7. OPTIONAL ACCESSORIES

7.1 FILTER INSTALLATION

There are no additional adjustments required after the CW filters have been installed.

If you do not have the TS-820 and/or TS-450 manuals, you can download them from my website at the following link:

TS-820 manual:

I just posted three pictures of audio spectrum analyzer software response curves for the TS820S YG88C filter. Not sure if I posted them properly or not.

In any event these were taken with diode noise bridge feeding the SO-239 and headphone jack driving my Lap Top computer thru a simple log pad so I dont overload the sound card. Spectrogram is the software. Very easy to use.

All three were run with Mode Switch in CW mode. One is with the IF Shift control at its center detent position, one with the IF Shift control at full Plus position, and one with the IF Shift at its full Minus position. I placed the markers at the approx center of each response curve.

When you buy any filter off Ebay or from just about any ham almost all will use "buzz" or "code" words like fully functional, worked last time I tried it, or was removed from working rig. I never install any used filter with out sweeping it before installing it. I use either Spectrum Analyzer with TG or Sweep Generator.

Before I had these tools I would do it the old fashioned way and inject RF around the IF frequency from a RF signal generator into the filter and measure the RF voltage at the filter output with O-scope or RF millivolt meter or RF probe and VTVM. Would then plot the voltage at each of the frequency steps on graph paper or plot with Excel. Of course the smaller and greater number of frequency steps that you use the better looking and more accurate graph you will have.

Possible to find that the filter FC has shifted or other issues.

Mike,
At times the Operators/Instruction Manual(s) are a bit lacking in descriptions/procedures. Are you able to get proper response/indications for Steps 5 & 6??
  When doing Step 7, are you flipping the SND/RCV switch to SND(send)? and are you connected to a dummy load??

Mike,

If everything has gone well up to this point (i.e. you got a nice dip with the meter in Ip in step 6), check the "RF METER CONTROL" pot on the top left of the back of the radio (looking from the back). This pot may be turned down and is used to adjust the RF meter to about 2/3 scale deflection for relative power indication when the transmitter is properly tuned in the CW mode. (page 12, item 2 in the Instruction Manual).

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Sunday net was run by me, WB0IQK. There were
24 stations checking in under good
conditions. There was 1 new station checking in, VE3US.

We had the following number of radios checking in.

5 running TS-520(x)
3 running TS-530(x)
3 running TS-820(x)
4 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
1 running TS-900

I was running my TS-830s + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
11 stations checking in under good conditions.

We had the following number of radios checking in.

4 running TS-520(x)
1 running TS-530(x)
1 running TS-820(x)
1 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-520s + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins
Nov. 2014 ☐ Oct 2015 Saturdays total 962 check-ins, Sunday total 669 check-ins

November 2015, Saturday☐s net total = 66, Sunday☐s total = 46
December 2015, Saturday☐s net total = 55, Sunday☐s total = 73
January 2016, Saturday☐s net total = 24 ,

If there is plate current that dips with the plate tuning try this,I would start with the RF Meter calibration control.There is a calibration control for the Relative RF meter, my TS520 has it with the VOX controls under the small side panel, other models may be on the rear panel. If this control is down too far CCW you will get a low reading or none. maybe the control is dirty nad has to be turned up and down a few times. My radio is Ham Radio...CW is Real Radio 73, John...K8JD

Subject: [TS-520_820_530_830] TS-830 Load Control

On page 18 of the operators manual, step 7 states: "place the meter switch to RF and peak the LOAD control"
When I do this, there is no deflection on the meter. I have been through the Survival Guide and Service Manual have found nothing on this topic. Any and all help is appreciated.Thank YouMike KG7YSH

The REL PWR meter pot is labeled "RF VOLT" and is located on the rear panel's upper left corner, just above the BIAS Pot. Refer to page 12 in the TS-830S Instruction manual, item "2".

There is no scale used for the REL PWR meter switch setting, only the position of the meter pointer.

The REL PWR meter is not a watt meter.

Once the transmitter is tuned for full power output into a 50 ohm dummy load, set the CAR control in CW mode for normal CW full power output then switch the meter switch to REL PWR and adjust the RF VOLT pot on the rear panel for a meter pointer indication of between 1 and 2 o'clock.

The meter indication may not be the same on all bands.

53798. DG-5 voltage

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-01-04 20:56:45 UTC
From: wbustraan@...
Topic: 53798 Message: 53798

Hello,

I am a new-ish ham and I was given a TS-520S with a DG-5 display. I have finally gotten an antenna up and I am beginning to start to learn how to operate the TS-520S, with the first thing step being listening around the bands.

I am having a hard time determining which exact frequency that I'm listening to for two reasons: A) the 0 marks on the dial and the subdial don't line up, so I don't know which dial to trust as being accurate, and B) when I plug in the DG-5 and turn on the radio, it displays zero for a fraction of a second and then goes dark.

However, I looked in the manual and it says that the DG-5 needs a power supply of 12-16V, nominal 13.8V. So I decided to try connecting the DG-5 to a 12V (car) battery. When I do, it lights up and seems to function just fine. Obviously, the battery isn't really a long term solution, so I'd like to figure out why it's not working with the TS-520S. I measured the voltage coming from the power connector on the back of the TS-520S and it reads around 15.2-15.4V.

Does anyone have some ideas as to what might be wrong?

Wes KD8SFN

The plug in question is a simple 3.5mm male mono plug which you can find on ebay. An example is eBay ad number 131190722217. Or you can purchase a 3.5mm male mono plug to RCA female socket such as on eBay ad number 131190719806 and use inexpensive audio cables found in DVR/DVD/VCR recorders/players. You can also find the 3.5mm mono plug at Radioshack.com under catelog number 2740868.

Measure the DC voltage at the Rectifier Unit's "14" terminal. That is where the rear panel DC voltage for the DG5 comes from.

If you do not have the TS-520S and/or DG5 Instruction and Service manuals, you can download them from my website

TS-520S Instruction Manual:
http://w5rkl.com/wp-content/uploads/2014/04/TS-520S-Operators-Manual.pdf
http://w5rkl.com/wp-content/uploads/2014/04/TS-520S-Operators-Manual.pdf

TS-520S Service Manual:
http://w5rkl.com/wp-content/uploads/2014/04/TS520S_service-manual.pdf
http://w5rkl.com/wp-content/uploads/2014/04/TS520S_service-manual.pdf

TS-520S High Resolution Schematic:
http://w5rkl.com/wp-content/uploads/2014/04/TS-520S_LARGE-Schematic_Hi-Res.pdf
http://w5rkl.com/wp-content/uploads/2014/04/TS-520S_LARGE-Schematic_Hi-Res.pdf

DG-5 Instruction Manual:
http://w5rkl.com/wp-content/uploads/2015/02/DG-5-operators-manual.pdf
http://w5rkl.com/wp-content/uploads/2015/02/DG-5-operators-manual.pdf

DG-5 Service manual:
http://w5rkl.com/wp-content/uploads/2015/02/DG-5-Service-Manual.pdf
http://w5rkl.com/wp-content/uploads/2015/02/DG-5-Service-Manual.pdf

You should not attempt to operate and/or service either the TS-520S or the DG-5 without reading/studying the manuals. Many problems can be averted and/or solved by studying the individual manuals.

Mike,

You should use shielded cable. A simple 2 conductor shielded cable has an outer braid which is ground and a center conductor which is not ground.

The cable's outer braid is connected to pin "4" on the 4 pin microphone plug.

The cable's center conductor is connected to pin 1 on the 4 pin microphone plug.

If you do not know which pin is 1 and 4 on the 4 pin microphone plug, review Fig 2-1 page 6 "Microphone Connection" in the TS-830S Instruction manual.

The 3.5mm mono plug terminals are shown in the following picture:

The above picture shows a small terminal with a "hole" in it. That is the "TIP" connection where the cable's center conductor connects to.

The above picture shows a long thin metal blade that wraps around the "shield" of the cable. That is "GROUND" which is the plug's "SLEEVE" where the cable's "braid" connects to.

The TS-830's transmitter is keyed using the SEND switch.

Following the SM220 manual's Section 5 "Operation" starting on page 9.

If you do not have the TS-830S and/or the SM220 Instruction and Service manuals then you should download both of them and spend time reading/studying them before you attempt to use the SM220 with your TS-830S.

SM220 Instruction manual:

Topic: 53798 Message: 53810

Certainly more investigation has to occur before a diagnosis is available.

Possibilities causing the issue may include:

1. A damaged or faulty regulator (there are two in the DG-5, one 5V and the other uses a pass transistor) drawing too much current for the TS-520 to supply. Try measuring the current the DG-5 draws from the battery. Considering the amount of TTL chips and the 7 segment LED displays, it will not be trivial.

2. Faulty circuit in the power supply in the 520 for the DG-5. Bad diode, bad filter cap (good possibility).

3. Possibly a faulty connector (bad contact) in the power connector (or power cable).

If I can get an opportunity, I will measure the voltage and current use of a DG-5 and get back to you. This will help locate the problem as a 520 issue or a DG-5 issue.

The suggestions I present are certainly not the only ones, just a place to start.

Good Luck,

Tim

I have an excellent cond. TS-530s, VFO-240 for sale. No scratches or dings. 2 faded spots in the paint where vfo sat on top of rig. Full output on all bands. Has narrow cw filter installed. Also includes Electro-Voice 638 mic. in very good cond. Rig performs flawlessly and the mic is a great match. Asking $550 plus shipping from 38606. I live in Batesville Ms. approx. 50 miles south of Memphis Tn. Would be willing to drive reasonable distance to meet up.
Also have Heathkit HD-1410 paddle keyer that I used with the rig. No scratches or dings. $65 includes original construction manual in very good cond. I have the original manual for the 530 also in very good condition. E-mail km5wx@bellsouth.net or call 662.563.0595 Thanks for looking

Ts-820s is in excellent cond. cosmetically. Rx is great won't transmit. It was slowly losing tx power and I was adjusting the bias voltage and must have done something wrong. It blew the fuse. After I replaced it the rx was fine but no tx. I'm sure some of you know exactly what went bad. Rig has narrow cw filter and also another Electro-Voice 638 mic. 2 RCA NOS 6146w tubes and original manual in good cond. go with it. I've never used the speaker. I assume it works but don't really know. It has 2 large scratches. One on either side like someone had it in a very tight spot. Would like $300 and same as with 530 shipping or travel reasonable distance to meet up. I assume the mic and cw filter are worth $150 all by themselves so I didn't think 300 was unreasonable. I have some other items that aren't Kenwood that I'm going to list on QTH.com so please look. Thanks again and e-mail or ph 662.563.0595 73 Richard KM5WX

53816. CW Filter testing? signal loss on narrow setting

I have a couple of 8.8 kenwood cw filters that I'd like to test on my spectrum analyzer... before I toss the in the rig (TS-830S).

anyone know the impedance so I can load some R across the input/outputs for the test jig so i can sweep it?
anyone else done this would like to share any experience?

I am seeing an S9 signal drop to about S1-2 when I switch into the CW mode (I have both 455/833 500 hz CW filters in place now) which is far too much to be normal. makes the narrow mode unusable. This has been the case since I installed them a while back, but now I gotta fix it. I came across a pair of 833 filters and wanted to test them before I tear into the rig just in case its the filter.

i need the CW narrow mode for Straight Key Century club events - which is when have a good reason to use the TS830 instead of the modern stuff.

recommendations on approach to fixing the loss problem? suggestions on where to probe/what to look for before I pull the IF board out to possibly replace the filter?

-bob, w9zv

Bob:

See Page 7 of the Third Edition of the Service Manual for the YK-88C and YK-88CN filter for all the specs. Input and output impedance is 600 ohms and Fc is 8830.7 khz.

Can terminate with resistive L-pad. 600 ohm series resistor and 50 ohm shunt resistor or just try using 600 series resistor.

On my website (www "dot" k9tw "dot" com) under the Photos tab I have a picture of sweeps of a YK88S1 not terminated and terminated with 560 ohm resistors.

Terry K9TW
